Security zSecure Admin and Audit for RACF
Version 1.13

User Reference Manual

LC14-7663-00

Security zSecure Admin and Audit for RACF
Version 1.13

User Reference Manual

LC14-7663-00

Note
Before using this information and the product it supports, read the information in Appendix C, "Notices," on page 1697.

November 2011

This edition applies to version 1, release 13, modification 0 of IBM Security zSecure Admin (product number 5655-T01), version 1, release 13, modification 0 of IBM Security zSecure Audit for RACF (product number 5655-T02), IBM Security zSecure Alert (product number 5655-T11), IBM Security zSecure Visual (product number 5655-T09), IBM Tivoli Compliance Insight Manager Enabler for z/OS (product number 5655-T15) and to all subsequent releases and modifications until otherwise indicated in new editions.

Contents

About this publication

This manual provides information about IBM Security zSecure Admin and Audit for RACF including:

- A guide describing how to use the product features from ISPF panels.
- RACF® administration and audit user documentation.
- Both general and advanced user reference material for the CARLa command language, the CKGRACF command language, and the SELECT/LIST fields.
- Instructions for installing and using zSecure Collect.

Intended audience

This publication is intended for systems programmers and administrators responsible for installing, configuring and monitoring security for RACF. Readers must be familiar with RACF concepts and commands.

What this publication contains

This manual describes zSecure running on a z/OS® platform. For information on running on the z/VM® platform, see the *IBM Tivoli zSecure Manager for RACF z/VM: User Reference Manual*.

This publication refers to the *IBM® Security Server, RACF component* as RACF.

In this publication, sections that include the word *Guide* in the title provide detailed information about using the product through an ISPF interface. These sections also provide some background information on RACF. The other sections of the manual contain reference material for more advanced users. The manual is written with the assumption that readers have a working knowledge of ISPF and RACF . You can also refer to the *IBM Security zSecure Admin and Audit for RACF: Getting Started Guide* for a tutorial and examples on the basic product functionality.

The following items are discussed in this manual:

- Chapter 1, "Introduction," on page 1 provides an overview of the product architecture and introduces the main menu options and line commands available through the zSecure ISPF interface.
- Chapter 2, "RACF Administration Guide," on page 51 introduces the functions available from the RA RACF Administration menu as well as the help desk functions.
- Chapter 3, "RACF Audit Guide," on page 255 explains how to use the zSecure Audit functions available from the AU Audit menu. Information includes instructions for migrating from the Data Security Monitor (DSMON) program to zSecure, auditing RACF security options and tables, RACF user, resource profiles, and CKGRACF, instructions on using zSecure to identify inconsistencies in the RACF database and to resolve common RACF problems. The chapter also provides an overview of sample audit reports that can be customized using CARLa Auditing and Reporting Language (CARLa).
- Chapter 4, "Resource reports," on page 383 describes the display and reporting options for RACF resources. There are dedicated options for reporting on TCP/IP configurations, z/OS UNIX, CICS, IMS, and DB2.

- Chapter 5, “System Audit Guide,” on page 425 explains the most important standard system reports. Both ISPF and batch reports are covered in this chapter.
- Chapter 6, “Library Audit Guide,” on page 529 discusses the library update report used to find and display changes to members of partitioned data sets.
- Chapter 7, “SMF and HTTP Reporting (Events menu),” on page 545 explains how to use zSecure for SMF processing and describes the SMF reports, which can be used to monitor user activity and MVS™ events. This chapter also provides additional information on unloading and selecting security data sets.
- Chapter 8, “RACF Offline,” on page 593 describes how to use the RACF Offline component to issue most RACF commands against an inactive RACF database.
- Chapter 9, “Merge Usage Guide,” on page 623 explains how the MERGE commands work and how to use them to compare and synchronize RACF databases.
- Chapter 10, “RACF Access Monitor,” on page 643 describes the Access Monitor program and explains how RACF administrators can use it to cleanup the RACF database. It also explains how the program can be used to evaluate the effects of changes to the RACF database before putting them into production.
- Chapter 11, “Calling zSecure,” on page 689 provides a detailed reference on how to use zSecure in batch mode. This section also provides information on unloading and selecting security data sets in this chapter.
- Chapter 12, “CARLa Command Language,” on page 713 is the reference chapter for the CARLa Auditing and Reporting Language (CARLa) for creating your own reports, to customize standard reports, or to perform certain actions such as making an unload file of the security databases.
- Chapter 13, “SELECT/LIST Fields,” on page 953 lists the fields you can use to generate reports.
- Chapter 14, “CKGRACF Command Language,” on page 1499 is the reference chapter for CKGRACF commands. CKGRACF allows a central security administrator to provide specific access rights to a local administrator. This ability means that local administrators do not need group special privileges which would probably allow them too much control over the security database. In addition, security administrators can make the divisions between authority levels more flexible.
- Chapter 15, “Problem Determination Guide,” on page 1573 discusses the most common problems and their solutions.
- Chapter 16, “zSecure Collect for z/OS,” on page 1591 discusses the zSecure Collect program that collects data on the connections in your I/O subsystem, as well as information on the way your z/OS system is configured.
- Chapter 17, “Setup and Library Commands,” on page 1641 describes how to set up and customize zSecure.

For information on zSecure messages and return codes refer to *IBM Security zSecure: Messages Guide*.

For information on product installation, security setup, and customization for all users at the same time, refer to *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

Publications

This section lists publications in the IBM Security zSecure library, prerequisite publications, and related IBM publications. It also describes how to access and order publications online.

Note: You can find information about the zSecure products for z/OS systems at http://publib.boulder.ibm.com/infocenter/tivihelp/v2r1/topic/com.ibm.zsecure.doc_1.13/welcome.htm.

IBM Security zSecure library

The following documents are available in the IBM Security zSecure library:

- *IBM Security zSecure: Release Information*

  For each product release, the Release Information topics provide information about new features and enhancements, incompatibility warnings, and documentation update information for the IBM Security zSecure products. Access the current version of the release information from the IBM Security zSecure Information Center at http://publib.boulder.ibm.com/infocenter/tivihelp/v2r1/index.jsp?topic=/com.ibm.zsecure.doc_1.13/welcome.html.

- *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*, SC14-7662-00

  Provides information about installing and configuring the following IBM Security zSecure components:

  – IBM Security zSecure Admin
  – IBM Security zSecure Audit for RACF, ACF2 and Top Secret
  – IBM Security zSecure Alert for RACF and ACF2
  – IBM Security zSecure Visual for RACF
  – IBM Tivoli Compliance Insight Manager Enabler for z/OS

- *IBM Security zSecure Admin and Audit for RACF: Getting Started Guide*, GI11-9162-00

  Provides a hands-on guide introducing IBM Security zSecure Admin and IBM Security zSecure Audit product features and user instructions for performing standard tasks and procedures. This manual is intended to help new users develop both a working knowledge of the basic IBM Security zSecure Admin and Audit for RACF system functionality and the ability to explore the other product features that are available.

- *IBM Security zSecure Admin and Audit for RACF: User Reference Manual*, LC14-7663-00

  Describes the product features for IBM Security zSecure Admin and IBM Security zSecure Audit. Includes user instructions to run the features from ISPF panels, RACF administration and audit user documentation with both general and advanced user reference material for the CARLa command language and the SELECT/LIST fields. This manual also provides troubleshooting resources and instructions for installing the zSecure Collect for z/OS component. This publication is only available to licensed users.

- *IBM Security zSecure Audit for ACF2: User Reference Manual*, LC14-7664-00

  Explains how to use IBM Security zSecure Audit for ACF2 for mainframe security and monitoring. For new users, the guide provides an overview and conceptual information about using ACF2 and accessing functionality from the ISPF panels. For advanced users, the manual provides detailed reference information including message and return code lists, troubleshooting tips, information about using zSecure Collect for z/OS, and details about user interface setup. This publication is only available to licensed users.

- *IBM Security zSecure Audit for ACF2: Getting Started Guide*, GI11-9163-00

  Describes the IBM Security zSecure Audit for ACF2 product features and provides user instructions for performing standard tasks and procedures such as

analyzing Logon IDs, Rules, and Global System Options, and running reports. The manual also includes a list of common terms for those not familiar with ACF2 terminology.

- *IBM Security zSecure Audit for Top Secret: User Reference Manual*, LC14-7665-00

  Describes the IBM Security zSecure Audit for Top Secret product features and provides user instructions for performing standard tasks and procedures.

- *IBM Security zSecure Alert: User Reference Manual*, SC14-7666-00

  Explains how to configure, use, and troubleshoot IBM Security zSecure Alert, a real-time monitor for z/OS systems protected with the Security Server (RACF) or CA-ACF2.

- *IBM Security zSecure Visual: Client Manual*, SC14-7669-00

  Explains how to set up and use the IBM Security zSecure Visual Client to perform RACF administrative tasks from the Windows-based GUI.

- *IBM Security zSecure Command Verifier: User Guide*, SC14-7670-00

  Explains how to install and use IBM Security zSecure Command Verifier to protect RACF mainframe security by enforcing RACF policies as RACF commands are entered.

- *IBM Security zSecure CICS Toolkit: User Guide*, SC14-7671-00

  Explains how to install and use IBM Security zSecure CICS Toolkit to provide RACF administration capabilities from the CICS® environment.

- *IBM Security zSecure: Messages Guide*, SC14-7667-00

  Provides a message reference for all IBM Security zSecure components. This guide describes the message types associated with each product or feature, and lists all IBM Security zSecure product messages and errors along with their severity levels sorted by message type. This guide also provides an explanation and any additional support information for each message.

- *IBM Security zSecure: Quick Reference*, SC14-7668-00

  This booklet summarizes the commands and parameters for the following IBM Security zSecure suite components: Admin, Audit, Alert, Collect, and Command Verifier. Obsolete commands are omitted.

- *IBM Security zSecure: Documentation CD*, LCD7-1387-09

  Supplies the IBM Security zSecure Information Center, which contains the licensed and unlicensed product documentation. The *IBM Security zSecure: Documentation CD* is only available to licensed users.

- *Program Directory: IBM Security zSecure Suite CARLa-driven components*

  This program directory is intended for the system programmer responsible for program installation and maintenance. It contains information concerning the material and procedures associated with the installation of zSecure CARLa-driven components: Admin, Audit, Visual, Alert, and the IBM Tivoli Compliance Insight Manager Enabler for z/OS. Program directories are provided with the product tapes. You can also download the latest copy from the IBM Security zSecure Information center available at http://publib.boulder.ibm.com/infocenter/tivihelp/v2r1/index.jsp?topic=/com.ibm.zsecure.doc_1.13/welcome.html.

- *Program Directory: IBM Security zSecure CICS Toolkit*

  This program directory is intended for the system programmer responsible for program installation and maintenance. It contains information concerning the material and procedures associated with the installation of IBM Security zSecure CICS Toolkit. Program directories are provided with the product tapes. You can also download the latest copy from the IBM Security zSecure Information center

available at http://publib.boulder.ibm.com/infocenter/tivihelp/v2r1/index.jsp?topic=/com.ibm.zsecure.doc_1.13/welcome.html.

- *Program Directory: IBM Security zSecure Command Verifier*

  This program directory is intended for the system programmer responsible for program installation and maintenance. It contains information concerning the material and procedures associated with the installation of IBM Security zSecure Command Verifier. Program directories are provided with the product tapes. You can also download the latest copy from the IBM Security zSecure Information center available at http://publib.boulder.ibm.com/infocenter/tivihelp/v2r1/index.jsp?topic=/com.ibm.zsecure.doc_1.13/welcome.html.

- *Program Directory: IBM Security zSecure Admin RACF Offline*

  This program directory is intended for the system programmer responsible for program installation and maintenance. It contains information concerning the material and procedures associated with the installation of the IBM Security zSecure Admin RACF Offline component of IBM Security zSecure Admin. Program directories are provided with the product tapes. You can also download the latest copy from the IBM Security zSecure Information center available at http://publib.boulder.ibm.com/infocenter/tivihelp/v2r1/index.jsp?topic=/com.ibm.zsecure.doc_1.13/welcome.html.

Related z/OS documentation

More information about RACF and the types of events that can be reported using zSecure Admin and Audit can be found in several IBM manuals. Information about the various types of events that are recorded by RACF can be found in the *RACF Auditor's Guide*. To access manuals in the z/OS online library, enter order numbers at the following URL: http://www-03.ibm.com/systems/z/os/zos/bkserv/.

Table 1. z/OS manuals in z/OS online library

Manual title	Order number
z/OS Security Server RACF Command Language Reference	SA22-7687
z/OS Security Server RACF Security Administrator's Guide	SA22-7683
z/OS Security Server RACF Auditor's Guide	SA22-7684
z/OS Security Server RACF System Programmer's Guide	SA22-7681
z/OS Communications Server IP Configuration Reference	SC31-8776
z/Architecture® Principles of Operation	SA22–7832

Accessing terminology online

The IBM Terminology website consolidates the terminology from IBM product libraries in one convenient location. You can access the Terminology website at http://www.ibm.com/software/globalization/terminology.

Accessing publications online

The documentation CD contains the publications that are in the product library. The format of the publications is PDF, HTML, or both.

IBM posts publications for this and all other Tivoli® products, as they become available and whenever they are updated, to the Tivoli Information Center website at http://www.ibm.com/tivoli/documentation.

Note: If you print PDF documents on paper that is not letter-size, set the print option that Adobe Reader uses to print letter-size pages on paper that is not letter-size.

Ordering publications

You can order many Tivoli publications online at:

http://www.elink.ibmlink.ibm.com/publications/servlet/pbi.wss.

You can also order by telephone by calling one of these numbers:

- In the United States: 800-879-2755
- In Canada: 800-426-4968

In other countries, contact your software account representative to order Tivoli publications. To locate the telephone number of your local representative, perform the following steps:

1. Select http://www.elink.ibmlink.ibm.com/publications/servlet/pbi.wss.
2. Select your country from the list and click **Go**.
3. Click **About this site** in the main panel to see an information page that includes the telephone number of your local representative.

Licensed publications: IBM Security zSecure licensed publications have a publication number that starts with an *L* , such as LC27-2781-00. To request a licensed publication, send an email to:

tivzos@us.ibm.com

. In the email include your IBM customer number, list of publication numbers, and your contact information. IBM contacts customers to complete orders. To contact IBM, see “Support for problem solving” on page xviii.

Accessibility

Accessibility features help users who have a physical disability, such as restricted mobility or limited vision, to use software products successfully. For keyboard access in the zSecure products, standard shortcut and accelerator keys are used by the product, where applicable, and are documented by the operating system. Refer to the documentation provided by your operating system for more information.

Visit the IBM Accessibility Center at http://www.ibm.com/alphaworks/topics/accessibility/ for more information about IBM's commitment to accessibility.

Tivoli technical training

For Tivoli technical training information, access the IBM Tivoli Education website at http://www.ibm.com/software/tivoli/education

.

Tivoli user groups

Tivoli user groups are independent, user-run membership organizations that provide Tivoli users with information to assist them in the implementation of Tivoli Software solutions. Through these groups, members can share information and learn from experienced Tivoli users. Tivoli user groups include the following members and groups:

- 23,000+ members
- 144+ groups

Access the Tivoli Users Group at http://www.tivoli-ug.org.

Support for problem solving

If you have a problem with your IBM software, you want to resolve it quickly. IBM provides the following ways for you to obtain the support you need:

Online
Navigate to the IBM Software Support site at http://www.ibm.com/software/support/probsub.html.

IBM Support Assistant
The IBM Support Assistant (ISA) is a free local software serviceability workbench that helps you resolve questions and problems with IBM software products. The ISA provides quick access to support-related information and serviceability tools for problem determination. To install the ISA software, navigate to http://www.ibm.com/software/support/isa.

Conventions used in this publication

This publication uses several conventions for special terms and actions, operating system-dependent commands and paths, and margin graphics.

Typeface conventions

This publication uses the following typeface conventions:

Bold

- Lowercase commands and mixed case commands that are otherwise difficult to distinguish from surrounding text
- Interface controls (check boxes, push buttons, radio buttons, spin buttons, fields, folders, icons, list boxes, items inside list boxes, multicolumn lists, containers, menu choices, menu names, tabs, property sheets), labels (such as **Tip:** and **Operating system considerations:**).
- Keywords and parameters in text

Italic

- Citations (examples: titles of publications, diskettes, and CDs
- Words defined in text (example: a nonswitched line is a *point-to-point line*)
- Emphasis of words and letters (words as words example: "Use the word *that* to introduce a restrictive clause."; letters as letters example: "The LUN address must start with the letter *L*.")
- New terms in text (except in a definition list): a *view* is a frame in a workspace that contains data.
- Variables and values you must provide: ... where *myname* represents....

`Monospace`

- Examples and code examples
- File names, directory names, and path names
- Message text and prompts addressed to the user
- Text that the user must type
- Values for arguments or command options

Chapter 1. Introduction

zSecure provides cost-effective security administration, improves service by detecting threats, and reduces risk with automated audit and compliance reporting. The product does this by increasing the functionality of your security system and reducing processing time. The clear structure and the possibility to make a more granular division between administration authority levels enable you to distribute the workload without compromising security.

zSecure runs on a z/OS or z/VM platform and uses RACF information and functionality.

Note: For an overview of the User Reference Manual content and other zSecure documentation, see "What this publication contains" on page xi.

General information

To better understand the zSecure products, it helps to have an overview of the program structure. The primary processing programs are large modules that can be used in batch or interactive mode. Interactive mode is most common, although batch mode can be useful for automated, periodic checks or for producing daily reports.

zSecure provides an interactive user interface implemented in ISPF using the *panel, skeleton* and *message* libraries supplied with zSecure. ISPF is the main program running during an interactive session, calling the zSecure application program as needed.Figure 1 on page 2 illustrates the general flow. The user completes tasks through ISPF panels, which generate commands that are sent to zSecure. These commands generate the RACF commands to alter the user ID as requested.

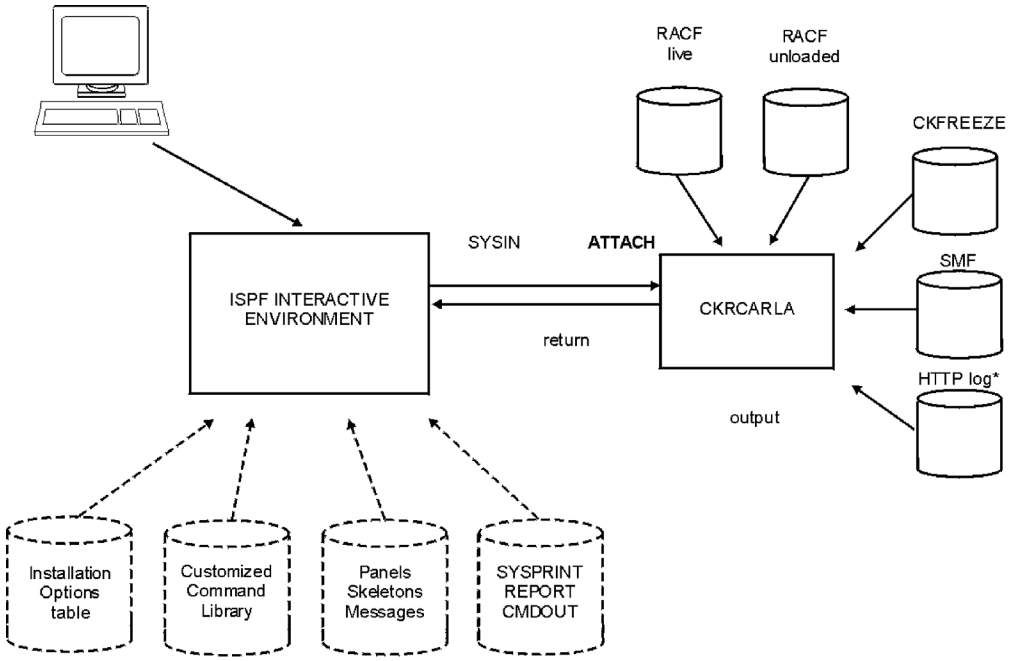

Figure 1. Conceptual Data flow

This general design with separate interactive and noninteractive components provides a number of practical advantages:

- It separates interactive interfaces from the application program. This separation allows more flexibility in designing and using the interfaces and programs, especially when customizing the ISPF interface.
- Any functions that can run interactively can also run in batch mode.
- An installation can create customized reports using the CARLa Auditing and Reporting Language (CARLa) program and run these reports from the ISPF panels or in batch.

zSecure is command driven using the CARLa program which is described in this manual. A typical user who runs zSecure from the ISPF user interface does not need to know the CARLa language because the code is automatically generated from the settings and selections specified on the product panels.

Because the standard, predefined zSecure reports are comprehensive, customized reports might not be required. However, you can customize the reports if necessary. Using zSecure in batch provides advantages from a security monitoring function. For example, you can set up a batch job to automatically run a set of zSecure checks and reports every day or every week rather than having a user set up and run the reports manually from the ISPF interface.

A comprehensive set of sample reports is available in a data set referred to as the CARLa library (ddname `CKRCARLA`, data set `SCKRCARL`).

Tip: See Chapter 11, “Calling zSecure,” on page 689 for a list of available CARLa scripts.

Data Sources

zSecure uses the following types of data and sources of data:

- Data from your security system which can be obtained from the local system and remote systems.
- Data which describes your system configuration (control blocks and DASD)
- Data describing events on your system (SMF)

The following figure shows the zSecure data input sources and data flow.

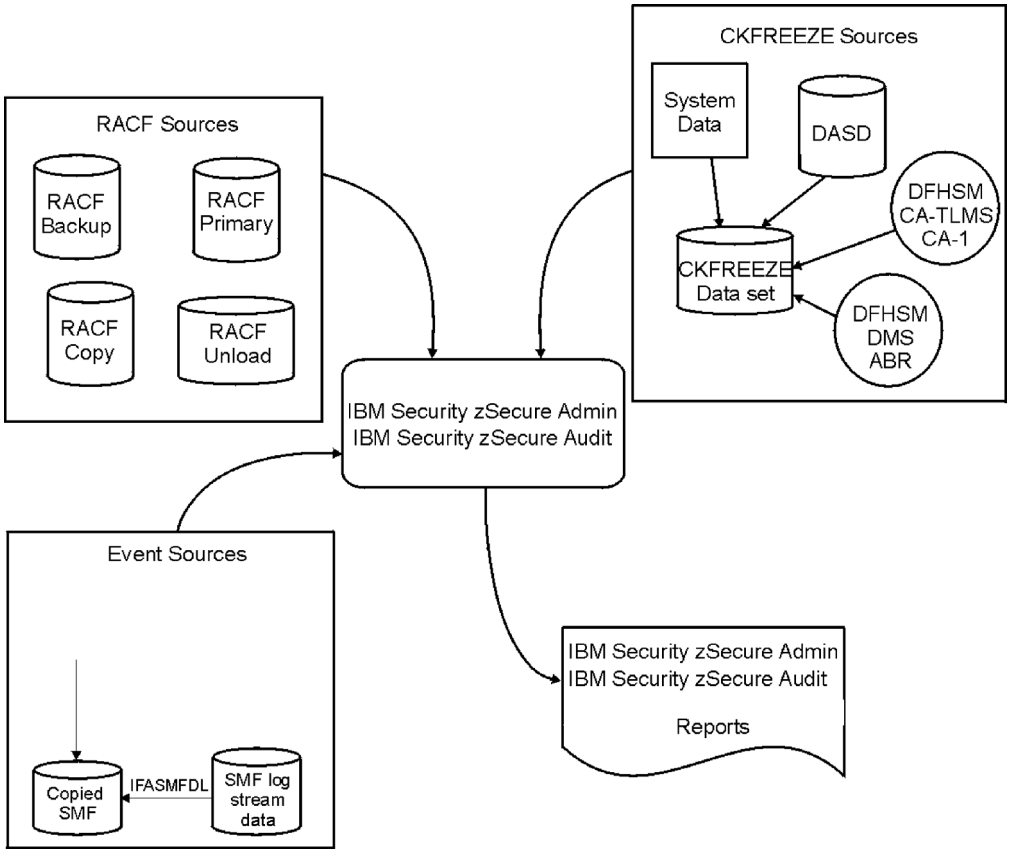

Figure 2. zSecure Input Sources

You define input sets that specify the data sources for zSecure from the "SE.1 Setup - Input files" on page 1645 menu option. For example, one input set might only contain the live security database. Another set might contain the live security database combined with a file containing system configuration data. Another set might use unloaded security data, system configuration data, and several SMF files. During a zSecure session, you can switch between input sets with the `SETUP` functions.

Data from your security system

zSecure usually requires RACF data that can come from four sources:

- Primary live RACF database
- Backup live RACF database
- Unloaded RACF data
- A copy of a RACF database, or an active RACF database from another system.

Note: zSecure creates an unloaded copy of RACF data by reading the live RACF database and creating a copy in a proprietary format suitable for high-speed

searches. The zSecure process is much faster and uses much less space than the RACF database unload program IRRDBU00.

You can use zSecure for the administration and auditing of profiles, resources, and settings from multiple systems. Beginning with zSecure release V1.12, you can configure the input data sources for systems of interest to collect the information directly from each system. The data sets can then be used through the ISPF interface or in a CKRCARLa program.

In addition to multisystem reporting, the product also supports routing commands to a remote system using zSecure services or existing RACF Remote Sharing Facility (RRSF) services. zSecure provides the following command routing options: Route to the local system, or route to a remote system using NJE batch jobs, RRSF services, or zSecure services. For additional information about command routing options, see "Using remote data."

Note: Support for working with data obtained directly from remote systems and remote command routing using either zSecure services or RRSF services is available beginning with zSecure V1.12. To use these functions, the zSecure Server component must be installed, configured, and activated. See *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

If you are using zSecure V1.11 or earlier, you can still report on data from multiple systems. However, you cannot obtain the information directly from a remote system. Instead, you must transfer the data sets containing information obtained from each system to a central system. Then, those copied data sets can be used as input to the CKRCARLA program, or as input files in the ISPF User Interface using the `SETUP FILES` function.

Using remote data

Beginning with V1.12, zSecure Admin and zSecure Audit support the use of remote data sets as input for creating reports and displays. This functionality is called multisystem support because it enables reporting and managing multiple systems from a single session. This function is also integrated with zSecure Admin support for routing RACF commands using zSecure services or RRSF services. Access to this functionality requires that the zSecure Server is installed.

Using zSecure services for remote data access requires the zSecure Server which runs in a separate server address space. The zSecure Server performs the necessary functions for command routing and communicating with remote systems to access RACF databases, SMF input files, CKFREEZE data sets, and other defined data sets. These functions only support input files from remote systems. Output files for the generated report data must be allocated on the local system.

For more information, see the following topics:

- "Reporting on data from remote systems"
- "Command routing" on page 5

Reporting on data from remote systems: Using remote data for creating reports is useful for ad-hoc reporting about profiles or settings. Because accessing large amounts of remote data is slower than accessing the same data locally, remote data access is less suited for queries that require processing of the entire security database or the entire `CKFREEZE` data set. If your query specifies a remote data source but does not specify a CKFREEZE data set with the same remote specification, a `CKFREEZE` data set describing the active configuration of the remote system is added automatically.

Using remote data for creating reports is useful for ad-hoc reporting about records or settings. Because accessing large amounts of remote data is slower than accessing the same data locally, remote data access is less suited for queries that require processing of the large quantities of data like the entire `CKFREEZE` data set. If your query specifies a remote data source but does not specify a CKFREEZE data set with the same remote specification, a `CKFREEZE` data set describing the active configuration of the remote system is added automatically.

You can specify the location of an input data source on a remote system using the `SETUP FILES` interface in the ISPF environment or the CARLa `ALLOCATE` statement. See Chapter 17, "Setup and Library Commands," on page 1641 and "ALLOCATE" on page 718.

Using remote data requires the following authorizations:

- Access to the remote destination.
- Access to the remote data set using the zSecure Server.
- For all data sets other than the live data sources, authorization to access the data set.

These authorizations must be established before you can access the remote data. The resources and profiles required for setting up these authorizations are described in *Setting up security for zSecure* in the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*. Contact your system administrator for additional information and assistance.

Command routing: When you are issuing commands that are generated by CKRCARLA, you can select how the commands are routed:

- Routing to the local system.
- Routing using zSecure services.
- Routing using RRSF services.
- Routing through NJE batch jobs.

You can also select if you want to specify the command routing for each and every command, or if you want to use default routing. If no explicit command routing is specified, commands are sent to the local system. For more information about command routing, see "SE.4 Setup - Confirm" on page 1655.

The authorizations required for command routing depend on the routing method specified:

- Routing using zSecure services requires authorization to the appropriate zSecure resources.
- Routing using RRSF services requires an approved user association The required RRSF authorizations are described in the *RACF Security Administrator's Guide* and the *RACF Command Language Reference*
- Routing through NJE batch jobs requires authorization to route jobs to the remote system.

These authorizations must be established before you can route commands to remote systems. The resources and profiles required for setting up these authorizations are described in *Setting up security for zSecure* in the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*. Contact your system administrator for additional information and assistance.

Data describing your system configuration (control blocks and DASD)

zSecure uses z/OS control block data and DASD data. These data are read from a CKFREEZE data set, created by zSecure Collect. “SE.2 Setup - New files” on page 1653 explains how to create a CKFREEZE data set. zSecure Collect uses APF-authorized functions to retrieve data from other address spaces and from read-protected common storage. zSecure Collect also reads all online VTOCs, VVDSes, catalogs, selected PDS and PDSE directories, UNIX file systems, and optionally calculates digital signatures at the member and data set level when requested. Additionally, batch collection permits you to analyze a remote system where the data was collected.

Data describing events on your system (SMF)

The SMF data can come from live SMF data sets, SMF log streams, or from sequential SMF data sets produced with the IFASMFDP or IFASMFDL programs. The IFASMFDP or IFASMFDL programs are provided by IBM to unload SMF records from the live SMF data sets and SMF log streams respectively. These sequential files can be on disk or tape, although many installations might not permit TSO users to mount tapes for interactive use. zSecure cannot process pseudo-SMF files created by the RACF REPORT WRITER or by the IRRADU00 SMF unload program.

zSecure User roles

zSecure provides functionality for different types of users. In this documentation, the following titles describe the different user roles. These descriptions are provided to clarify the zSecure specification of these roles in case your organization has different titles or descriptions for a task.

Central Security Administrators
The employees who are responsible for the system-wide administration of the mainframe security systems. They have extensive knowledge of security administration and of the mainframe environment. These people are responsible for creating and, possibly, implementing the company standards.

System Programmers
People involved with the running of the mainframe environment. If they are also involved with the security they probably have the same detail level of knowledge as central security administrators.

Decentralized / local Administrators
Technical people on local or decentralized level with a fair knowledge about the mainframe security systems. They are responsible for the proper running of the security systems at their level or department. They work within the settings made by the centralized administrator but might have great freedom within these settings.

Auditors
People with a good knowledge about security matters but not necessarily about the technical part of the security systems. They audit the system and report to the administrators.

Local Security Administrators
Local Security Administrators such as help desk employees are responsible for administrative task such as resetting passwords, copying users, and so on.

The IBM Security zSecure products

IBM Security zSecure suite is a group of products that improves the efficiency and maintainability of your mainframe security environment. The main products are zSecure Admin and zSecure Audit. These products can be used separately or in combination with the other zSecure products.

The following descriptions are intended to provide a brief overview of the products. More detailed information about zSecure Admin and Audit is available from other topics in this documentation. For additional information about any of the other zSecure products, refer to the documentation for those products.

zSecure Admin
Provides a user-friendly layer in the form of an ISPF interface on top of RACF and extends the functionality so users can enter and process administrative commands more quickly, generate custom reports, and thoroughly clean up security databases. zSecure Admin also provides administrative authority in a more granular fashion so people only have the specific amount of administrative authority required for their job.

zSecure Audit
Compliance and audit solution that enables you to automatically analyze and report on security events and detect security exposures. It provides standard and customized reports that warn of policy exceptions or violations. This component is available for RACF, ACF2, and Top Secret.

zSecure Alert
Mainframe audit solution that enables you to detect and report security events and exposures on z/OS systems protected with RACF or ACF2 that issues alerts for important events relevant for the security of the system at the time they occur.

zSecure Visual
zSecure Visual is comprised of two components: a client and a server. zSecure Visual client is a Windows-based graphical user interface for RACF administration. zSecure Visual server establishes a secure connection directly with RACF to enable decentralized administration from a Windows® environment.

Tivoli Compliance Insight Manager Enabler for z/OS
IBM Tivoli Compliance Insight Manager Enabler for z/OS is an optional component. You can use it to connect the mainframe to the cross-platform auditing and compliance solution IBM Tivoli Compliance Insight Manager or Tivoli Security Information and Event Manager. When this option is configured, mainframe events and alerts can be managed centrally from an enterprise compliance dashboard for reporting across applications, databases and operating systems.

zSecure Command Verifier
Mainframe policy enforcement solution that adds granular controls for RACF to help prevent errors and noncompliant commands. This product runs in the background to verify your RACF commands against company policies and procedures. If the command does not comply with the policy, it is blocked or fixed. It can run independently from the other zSecure components.

zSecure CICS Toolkit
Enables most RACF administration activities from a CICS environment which can be used instead of TSO.

zSecure Manager for RACF z/VM
Simplifies the process of managing mainframe security and enables you to quickly identify and fix problems in RACF on z/VM. zSecure Manager for RACF z/VM automates recurring and time-consuming security tasks.

Note:

This manual only provides documentation for zSecure Admin and Audit for RACF. For information about other zSecure products, see "IBM Security zSecure library" on page xiii.

zSecure key programs

The following descriptions are intended to provide a brief overview of programs that provide key functionality within the IBM Security zSecure products. More detailed information about programs for zSecure Admin and Audit is available from other topics in this user documentation. For additional information about zSecure Visual or any of the other zSecure products, see the documentation for those products.

C2PACMON
The `C2PACMON` program is the main program for the Access Monitor for RACF monitor which provides RACF administrators with the data required to remove unused or obsolete resource profiles and authorizations defined within profiles. This function is used for RACF database cleanup. The Access Monitor also allows RACF administrators and analysts to run simulations against a candidate RACF database to test resource profiles and the access rights defined within them.

C2POLICE
This program is the main program of the zSecure Alert address space. It intercepts SMF records and WTO messages to detect events that require alerts to be sent out to system operators, security administrators and/or security personnel via for instance EMAIL or SMS messages.

CKGRACF
The `CKGRACF` program is part of zSecure Admin. It is used for handling Queued commands (like temporary access), revoke or resume schedules, User data fields and various other functions that require updating RACF profiles. This program is also used by zSecure Visual.

CKNSERVE
The `CKNSERVE` program is the main program for the zSecure Server which performs the necessary functions for communicating with remote systems to route commands and access RACF databases, SMF input files, `CKFREEZE` data sets, and other defined data sets. For more information, see "Using remote data" on page 4.

CKRCARLA
The CKRCARLA program is the main program used in zSecure products. Using the special purpose CARLa Auditing and Reporting Language (CARLa), the CKRCARLA program processes SMF, CKFREEZE data, and other types of information. The program is used by the following zSecure products: Admin, Audit, Alert, Visual, and the Tivoli Compliance Insight Manager Enabler for z/OS.

zSecure RACF Exit Activator
The zSecure RACF Exit Activator, `C2XACTV` provides dynamic exit support for some RACF exits. The main purpose of the RACF Exit Activator program is to

install exits required by various zSecure products. This program supports the following products: IBM Security zSecure Admin and Audit, and Alert and Tivoli Compliance Insight Manager Enabler for z/OS. For additional information about the program, see Chapter 11, "Calling zSecure," on page 689. For details on installing the zSecure RACF Exit Activator program, see the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

RACF Offline
IBM Security zSecure Admin provides the RACF Offline function to allow you to execute and test RACF commands on a RACF database that is not active in the system. Using this program, you can test changes to RACF definitions without impacting any other software executing on the system and without using a dedicated test system.

zSecure Collect
The zSecure Collect program, `CKFCOLL` gathers information about your z/OS system configuration. Designed to collect data quickly using minimal system resources, this program does not provide any reporting functions other than some messages and a summary report. Analysis of the collected data is done by the CKRCARLA program. For more information, see Chapter 16, "zSecure Collect for z/OS," on page 1591.

Starting the interactive component

Typically, users complete zSecure work from the zSecure user interface. The user interface is implemented using an ISPF application available under TSO on z/OS. Depending on how the system administrator has configured the product, you can start zSecure by selecting the option from a menu or by entering a custom command. Ask your system administrator for instructions.

If the zSecure was installed using the default configuration and settings, the product can be started from TSO on z/OS under ISPF by using the implicit TSO EXEC command. That is, you can start zSecure by typing the following command on any ISPF command line:

```
TSO CKR
```

After this, the primary option menu is displayed.

Note: You can run multiple instances of zSecure in ISPF split-screen mode provided that all zSecure instances are the same version.

Other methods to invoke zSecure, including in batch and through TSO line mode commands, are described in Chapter 11, "Calling zSecure," on page 689.

Panel structure

When you start an interactive zSecure session the **main menu** is shown. This **main menu** contains an overview of the available options. Exactly which options are displayed depends on several factors. Options that are disabled or not installed are not shown. Options for which you do not have enough authorization are not shown. Moreover, your system administrator can remove or rename some options.

The initial look of the **Main menu** is shown in the following figure.

```
  Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                      zSecure Admin+Audit - Main menu
Option ===> ____________________________________________________________

 SE   Setup           Options and input data sets
 RA   RACF            RACF Administration
 AU   Audit           Audit security and system resources
 RE   Resource        Resource reports
 AM   Access          RACF Access Monitor
 EV   Events          Event reporting from SMF and other logs
 CO   Commands        Run commands from library
 IN   Information     Information and documentation
 LO   Local           Locally defined options
 X    Exit            Exit this panel

Input complex: Active primary RACF data base
```

Figure 3. Security zSecure main menu on entry

The options on this panel are called *primary* options. Some options expand when you select them. Figure 4 shows a sample of the expanded main menu. Notice that the primary options are still available.

```

 AM   Access          RACF Access Monitor
 EV   Events          Event reporting from SMF and other logs
```

Figure 4. zSecure main menu after selecting option RA

Using the UP- and DOWN-keys shows the rest of the menu.

Security zSecure remembers the last menu option you expanded. When you start a new session, the session starts with that menu option expanded.

Additional information about using the panels is available in “A sample run” on page 17. Table 2 provides an index to the documentation for the Menu options. See “IN INFORMATION - Information and documentation” on page 35 for additional documentation overview information.

Table 2. Documentation references for zSecure Menu options

Menu option	Documentation reference
SE Setup	Chapter 17, “Setup and Library Commands,” on page 1641
RA RACF	Chapter 2, “RACF Administration Guide,” on page 51
AU Audit	Chapter 5, “System Audit Guide,” on page 425
RE Resources	Chapter 4, “Resource reports,” on page 383
AM Access	Chapter 10, “RACF Access Monitor,” on page 643
EV Events	Chapter 7, “SMF and HTTP Reporting (Events menu),” on page 545
CO Commands	Chapter 17, “Setup and Library Commands,” on page 1641
IN Information	“IN INFORMATION - Information and documentation” on page 35
LO Local	“LO LOCAL - Locally defined options” on page 35

Primary commands

Primary commands can be entered at the command prompt (**===>**) on panels. Security zSecure supports the following primary commands.

ACCESS
The `ACCESS` command displays a panel to test the access of a third-party user or group to a resource. For more information, see the `CKGRACF ACCESS` command in Chapter 14, “CKGRACF Command Language,” on page 1499.

ACL
Use the ACL command to change the format and sort order of access lists (ACLs). You can enter this command on any display panel that has an access list. For RACF access lists, see “Access list display modes - reference material” on page 30.

C2RIMENU
This command is only meant to be used for problem determination. It can be used to display the results of the authority checks for the menu options to be shown and the actions to be shown on the menus. It is only enabled when the SETUP TRACE option `Debug action commands` is active. See “SE.T Setup - Trace” on page 1673 and “Debugging menu option and action character problems” on page 1580.

CARLA or COMM
Type CARLa commands.

CKXDEBUG
Display CKX diagnostic information. This command is only for problem determination. It is enabled only when the `SETUP TRACE` option *Collect CKX diagnostic* information is active. See “SE.T Setup - Trace” on page 1673.

CKNSERVE
Displays information about the zSecure Servers that are known to the zSecure Server address space identified by the ServerToken parameter on the CARLa OPTION command. See “ServerToken” on page 866.

COLS
Use the COLS command to show a ruler in the top of your screen. This ruler

simplifies determining the start or end column number where certain information can be found. These column numbers are frequently used on for example FIND commands. Use the command COLS OFF to remove the ruler when you no longer need it. The command abbreviation for `COLS` is `COL`.

FIELDS
Show all fields that can be used in CARLa queries, as described in "FIELDS - Show CARLa fields available" on page 35. The command abbreviation for FIELDS is FIELD.

FIND
Use the FIND command to perform a character string search for text in a display panel. The search includes all scrollable information in the report portion of the panel. The search excludes information in panel headers. The command abbreviation for FIND is F. To repeat the previous search, use RFIND command (PF5 key).

The FIND command supports parameters to define the following search characteristics: scan direction, starting point, column delimiters, and case-sensitivity.

Specifying the search argument
The character string text is the first argument of the FIND command. For example, to search for the string `ADGRANT`, at the panel command prompt, enter `FIND ADGRANT`.

In the search results, the cursor is positioned on the first character of the character string.

Strings that contain special characters, such as blanks, must be delimited with quotation marks (") or apostrophes(') for example: `'AD GRANT'`. Delimiters are required for special characters, but can be used on any search string.

Specifying parameters to indicate the start point and scan direction of the search

- **FIRST**

  Starts the search on the first line of the report and searches from top to bottom. The RFIND command (PF5) starts from the previous occurrence of the character and continues searching down.
- **LAST**

  Starts from the last line of the report and searches from bottom to top. The RFIND command (PF5) starts from the previous occurrence of the character string and continues searching up.
- **NEXT**

  Starts from the current cursor position and finds the next occurrence of the search argument. The search direction is top to bottom and left to right. The default setting is NEXT.
- **PREVIOUS**

  Starts from the current cursor position and finds the previous occurrence of the search argument. The search direction is bottom to top and right to left.

Specifying parameters to limit the screen columns included in the search

- **Use a column name**

  Limits the search to a single column. For example, to search for AD GRANT in the Name column only:

```
FIND 'AD GRANT' Name
```

- **Use one numerical limit**

  Limits the search to search arguments starting only on that character column. Note that the COLS primary command can be used to determine the character column position. For example, to search for AD GRANT only starting on character column 5:

  ```
  FIND 'AD GRANT' 5
  ```

- **Use a low and high numerical limit**

  Limits the search to search arguments occurring between two limits. Note that the COLS primary command can be used to determine the character column position. For example, to search for AD GRANT between character columns 10 and 25:

  ```
  FIND 'AD GRANT' 10 25
  ```

Specifying search parameters for case-sensitivity

The CAPS and ASIS parameters in combination with a literal-string search argument allow you to define case-sensitive and case-insensitive searches.

- **CAPS**

  The CAPS parameter is the default. If this parameter is used, or the ASIS parameter is not used, the search is case insensitive.

- **ASIS**

  The ASIS parameter is used for upper case searches and case-sensitive searches.

If the search argument is specified with quotes and prefixed by a C character to indicate a literal string, the search is case sensitive. For example to search for the string `Ad Grant`, enter:

```
FIND C'Ad Grant' ASIS
```

FORALL

Use the following procedure with the FORALL command to issue a command for all or selected profiles on a record-level display. The command abbreviation for FORALL is FOR.Use the following procedure with the FORALL command to issue a command for all or selected records on a record-level display. The command abbreviation for FORALL is FOR.

1. On a profile overview panel, the User Profile Overview panel (**RA.U**) panel for example, use the select (**Z** or **ZZ**) and exclude (**X** or **XX**) line commands to select the set of profiles you want to run the command on. See "Z - Select a profile" on page 74 and "X - Exclude profile line command" on page 74.

   If no selections are made, then all profiles are processed.

2. On command line, use one of the following methods to specify the command to be run:

   - Type the command directly behind the FORALL command as shown in the following example. Use the substitution variables described in Table 3 on page 14 to specify the command to run.

     ```
     FORALL LISTUSER !KEY  /* CLASS=!CLASS */
     ```

   - If the command is too long or if you want to reuse the command for other selections, type FORALL on the command line. Then, press **Enter** to open the FORALL Command Shell panel to specify the command.

     This panel is like the ISPF option 6 (TSO command shell) for entering commands that can be recalled for future use.

Depending on the SETUP CONFIRM options specified for your environment, the commands are either run immediately or queued in the CKRCMD file for viewing and editing before you submit them for processing.

Figure 5 shows a sample FORALL command to list the user profile for selected profiles on the User Profile Overview panel (**RA.U**).

```
zSecure Suite USER overview                              1 s elapsed, 0.5 s CPU
Command ===> FORALL LISTUSER !KEY  /* CLASS=!CLASS */_______   Scroll===> PAGE
Users like PYRL*                                  2 Sep 2010 20:59
   User     Complex  Name                 DfltGrp  Owner    RIRP SOA gC LCX Grp
__ PYRLAA1  SYS1     ANTONE ANDER         PYRL     PYRL     ____ ___          5
zz PYRLAA2  SYS1     ANTONE ANDER         PYRL     PYRL     ____ ___          5
__ PYRLAHI  SYS1     ANSEL HILLENBRA      PYRL     PYRL     RI   ___       X   1
zz PYRLAH2  SYS1     ANSEL HILLENBRA      PYRL     PYRL     RI   ___       X   1
__ PYRLBM2  SYS1     BILL MCMASTER        PYRL     PYRL     ____ ___          6
```

Figure 5. FORALL command for listing user profiles

In this example, the following command is run for all profiles in the selection block marked with the **ZZ** line command.

```
FORALL LISTUSER !KEY  /* CLASS=!CLASS */
```

The !KEY variable is replaced by the profile key of each of these users. This value is shown in the **User** column. The /* CLASS=!CLASS */ specification generates a comment that is appended to the LISTUSER command generated for each selected profile. For user profiles, !CLASS=*USER* for all profiles.

When this command is issued, it generates the following commands.

```
LISTUSER PYRLAA2 /* CLASS=USER */
LISTUSER PYRLAHI /* CLASS=USER */
LISTUSER PYRLAH2 /* CLASS=USER */
```

These commands are processed based on the SETUP CONFIRM options specified for your environment.

Table 3 shows the substitution variables available to specify the parameters for FORALL command processing. In the FORALL command, the following symbols have special meaning:

- Substitution variables are indicated by an exclamation point (!) immediately followed by a variable identifier that consists of letters, digits, national characters, hyphens, and underscores.
- A period (.) immediately following an identifier is interpreted as a separator, !KEY. for example.

If you want the actual exclamation point or period to be included in the command string, repeat the symbol, for example: !!. A double symbol is not interpreted as the beginning of a substitution variable or a separator. Other than scanning for exclamation points, the command is run in the same form specified in the FORALL parameter. It is not parsed in any way.

Table 3. FORALL command - Substitution Variables

Substitution Variable	**Meaning**
!CLASS	Represents the profile class. For example, on the User Profile Overview panel (**RA.U**) menu option, a FORALL command that includes !CLASS always replaces that variable with USER.
!GENERIC	Substitutes the word GENERIC for fully-qualified generic profiles only.

Table 3. FORALL command - Substitution Variables (continued)

Substitution Variable	Meaning
!KEY	Represents the profile key. For example, on the User Profile Overview panel (**RA.U**), the following command for user profiles issues a LISTUSER command for each profile. `"FORALL listuser !KEY"` For DATASET class profiles, quotes are added to comply with TSO command syntax. The !KEY for DATASET class profiles is the data set name. For MEMBER and R_AC1, the !KEY is the member name, and for DSN and SENSDSN, the !KEY is the data set name. For TRUSTED, the !KEY can be a RACF profile.
!KEY_MODIFIERS	Modifiers to disambiguate the profile key. For example, on the Data set overview panel (**RA.D** menu option), the following command issues the LISTDSD command for each profile. `FORALL listdsd da(!key) !key_modifiers` The !key_modifiers parameter provides the GENERIC keyword where needed for fully-qualified generic profile as well as the VOL(...) clause for discrete profiles.
!TYPE	Indicates the profile type, GENERIC or NONVSAM for example.
!VOLSER	The volume serial disambiguates the key of a discrete profile. This substitution variable does not include the VOL(and) parts that are present in !KEY_MODIFIERS.

HELP

The HELP command is equivalent to the PF1 key. You can ask for help at any time. Most important screens have context-sensitive help. Other screens present the application tutorial. To get help on a field, position the cursor on the field or column and press PF1. To get help on a panel, position the cursor on the command line in the ISPF panel. Then, press PF1.

MESSAGE, MSG, or MSGS

Show the message library, or look up a message. The explanatory text displayed is documented in the *IBM Security zSecure: Messages Guide*.

Example:

The following command looks up message CKR0010 in the Security zSecure message library.

```
MSG 10
```

The following command looks up message CKF039I in the zSecure Collect message library.

```
MSG CKF039I
```

The following command looks up message CKG100I in the zSecure Collect message library.

```
MSG CKG100I
```

MODIFY

Use the MODIFY command to enable or disable the ability to change values of modifiable fields. The MODIFY command accepts the parameters ON or OFF. The

command abbreviation for MODIFY is M. If `MODIFY` is entered without a parameter, it reverses the current `MODIFY` setting.

PRT, PRTLIST
Create a hardcopy of a display, written to the standard ISPF LIST data set. This command is available only on display panels. You can print the LIST data set from any ISPF panel by issuing the `LIST` primary command. The ISPF LIST command can also be issued from outside Security zSecure.

RACF
Use the `RACF` command from zSecure display panels to open the RACF ISPF panels. When you are done working in the RACF ISPF panels, enter the `END` command or press `PF3` to return to the zSecure display panel.

RESET
Use the `RESET` command to remove all pending updates from display panels and cancel pending commands. One common use of this command is to remove an incorrect entry in a modifiable field and reset the incorrect entry to the original (valid) entry. The command abbreviation for RESET is RES.

RESULTS
Use the `RESULTS` command from menu and selection panels to open the Results panel. On the Results panel, you can choose to view results from the last query, any commands generated, the message output, and so on. The command abbreviation for RESULTS is RESULT. For more information, see "RESULTS - View output and results" on page 24.

RFIND
Repeat the previous FIND command from the current cursor position. This command is available only on display panels. Usually, you can also use F5 key to run the RFIND command.

SET
Use the `SET` command as an alternative way to change some options on the Setup - View and Setup - Confirm display panels. When you issue the SET command on a display panel, the changed options are applied immediately. For more information, see "SE.5 Setup - View" on page 1659 and "SE.4 Setup - Confirm" on page 1655.

SETUP
Invoke the SETUP application, as described in Section "SE SETUP - Options and input data sets used" on page 1641. Specify a number from the SETUP option menu to go directly to that option, SETUP 1 for example to select a different input source. The options are also available by name. For example, type SETUP FILES to select a different input source.

SORT
Use the `SORT` command on record-level display panels to sort results. The command abbreviation for SORT is SO. By default, result lines are sorted alphabetically in ascending order starting with the left column, in this example: **Userid**, then **Name**, **More data**, and **Even more data**.

Userid	Name	More data	Even more data
KEY1	MY_NAME	OTHER_VALUE	BREAD
KEY2	HIS_NAME	MORE_VALUES	HALIBUT
KEY3	HIS_NAME	NEW_VALUE	SODA

To sort result lines using any other column, enter the column name followed by the sort order: `A` or `ASCENDING`, or `D` or `DESCENDING`. For example, `SORT "Name" Ascending` produces the following results:

Userid	Name	More data	Even more data
KEY2	HIS_NAME	MORE_VALUES	HALIBUT
KEY3	HIS_NAME	NEW_VALUE	SODA
KEY1	MY_NAME	OTHER_VALUE	BREAD

To sort result lines using multiple columns, for example, `SORT "Name" A "More data" D` produces the following results:

Userid	Name	More data	Even more data
KEY3	HIS_NAME	NEW_VALUE	SODA
KEY2	HIS_NAME	MORE_VALUES	HALIBUT
KEY1	MY_NAME	OTHER_VALUE	BREAD

The `SORT` command cannot be used on detail display panels; instead, use the `ACL SORT` command. The `SORT` command cannot be used on static ISPF section panels.

STARTPAN
Specify the panel that opens when zSecure starts. See Section "Start Panel - Setting your favorite menu as the entry panel" on page 1641 for more information about start panels.

SYSPREV
Use the `SYSPREV` command to browse the `SYSPRINT` message file of a recursive query. You can enter the `SYSPREV` command from any display panel if the last task used a recursive query.

SYSPRINT
Use the `SYSPRINT` command to browse the message output file of the report generated from the last query. Exit the generated report by using `PF3` or `END`. Issue the `SYSPRINT` command from a menu or selection panel. An error displays if you enter `SYSPRINT` from the panel on which the generated report is displayed.

TEMPLATE
Show the contents of the RACF database templates, as described in Section "TEMPLATE - Template field properties" on page 284.

A sample run

As a first introduction to Security zSecure, this section presents a sample run. You can try running this sample on your system to see what happens. In this example, you learn how to view the user profiles and change them. You also learn how to use the commands generated by Security zSecure.

For additional information about a panel, press the `PF1` key to access the online help. To get information about a particular field or column, place the cursor on the field or column, then press `PF1`.

First, set the Security zSecure *options* for this example, in order to prevent any unwanted changes to the RACF database. Type **SETUP CONFIRM** or go to **SE.4** and enter all options as displayed in the following figure. The meaning of these options is explained later. When you exit the Security zSecure program, these options are automatically saved for the next session.

```
  Menu         Options       Info    Commands     Setup
_______________________________________________________________________________
                          zSecure Suite - Setup - Confirm
Command ===> _____________________________________________________________________

Action on command . . 1  1. Queue    2. Execute  3. Not allowed
Confirmation  . . . . 4  1. None     2. Deletes  3. Passwords      4. All
Command Routing . . . 3  1. Ask      2. Normal   3. Local only

Command generation
Enter "/" to select option(s)
/  Overtype fields in panels
/  Change generated commands
/  Specify start/end date
/  Generate SETROPTS REFRESH commands
   /  Issue prompt before generating SETROPTS REFRESH commands
Commands to generate
/  RACF commands
/  CKGRACF commands
/  CKGRACF ASK for later execution
/  CKGRACF REQUEST for later execution
_  CKGRACF WITHDRAW queued commands
/  CKGRACF RDELETE commands
```

Figure 6. Setup Confirm Menu

Press **End** when you are done to return to the main menu.

Select the RACF ADMIN selection menu by typing **RA** on the command line of the main menu; then press ENTER. You see the RACF ADMIN selection menu; these menus are used to select and display RACF profiles. Now type **U**. You see the USER SELECTION panel, displayed in Figure 7.

```
  Menu   Options   Info   Commands   Setup
-------------------------------------------------------------------------------
                          zSecure Suite - RACF - User Selection
Command ===> _____________________________________________     start panel

_   Add new user or segment

Show userids that fit all of the following criteria
Userid  . . . . . . *________    (user profile key or filter)
Name  . . . . . . . _____________________________ (name/part of name, no filter)
Installation data . _____________________________ (data scan, no filter except *)
Owned by  . . . . . _________    (group or userid, or filter)
Default group . . . _________    (group or filter)
Connect group . . . _________    (group or filter)

Additional selection criteria
_  Other fields       _  Attributes       _  Segment presence  _  Absence

Output/run options
_  Show segments      _  All              _  Specify scope
_  Print format       _  Customize title  _  Send as e-mail
   _  Background run  _  Full page form   _  Sort differently  _ Narrow print
```

Figure 7. Display User Menu

This is the basic selection panel, additional selection panels are shown when you select (/) any of the fields under "Additional selection criteria". The additional selection criteria are used only when you select the fields, but the selections are remembered as long as you are using the RA.U option.

The User Selection panel selects user IDs that match your search criteria. For now, do not specify anything. Press ENTER. IBM Security zSecure prompts for confirmation that you want to scan the whole database by putting an asterisk in

the **Userid** field and displaying the message `Default prompting`. By pressing ENTER a second time, the query starts, and presents a display with the results. A sample display is shown in Figure 8.

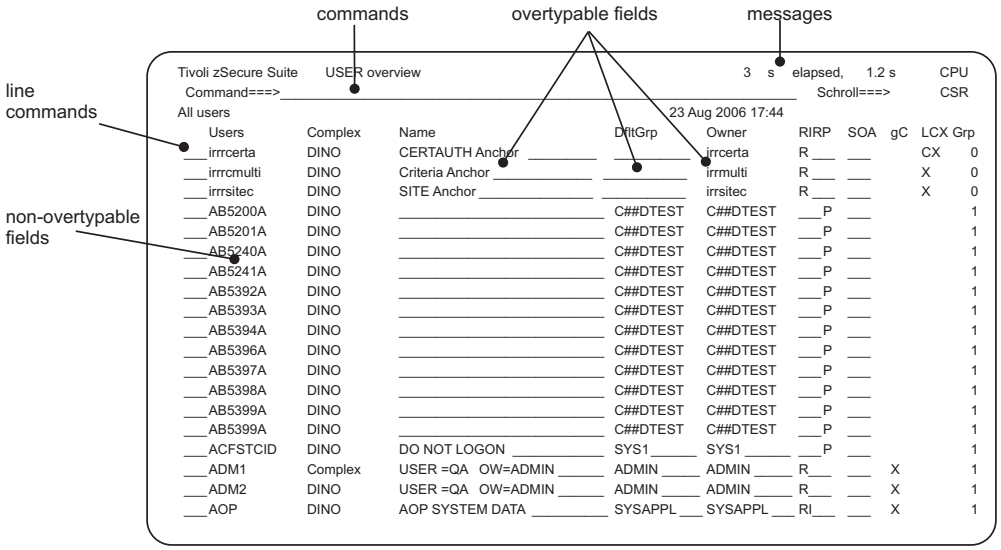

Figure 8. Overview Display

This display is an *overview* or *record* display, in which each profile is displayed on a single line. Scroll up and down, or left and right, to view more information. (A *detail* display showing one profile in detail also exists; more about this later.)

In the line command position in front of each user ID, you can issue a one- or two-character command. On the overview panel, a line command works on the entire profile. Several line commands are available for use depending on your authorization level, the installed and active Security zSecure product components, and the profile type. To see the available line commands in a popup window, type a slash (/) in front of the userid.

Also note the fields indicated as *modifiable fields*, for example the **Name** field. Modifiable fields are highlighted or shown in a different color depending on your CUA settings. You can change the settings with the ISPF primary command **CUAATTR**. If you type a new value over a modifiable field and press **Enter**, Security zSecure generates a command to change the profile to the new value.

To show command generation, change a user name (**Name**). Then, press **Enter**. A command confirmation panel is displayed to accept or cancel the command. For example, Figure 9 on page 20 shows the configuration panel that shows if the name for `userid` *ADGRANT* is changed to *ARTHUR GRANT*.

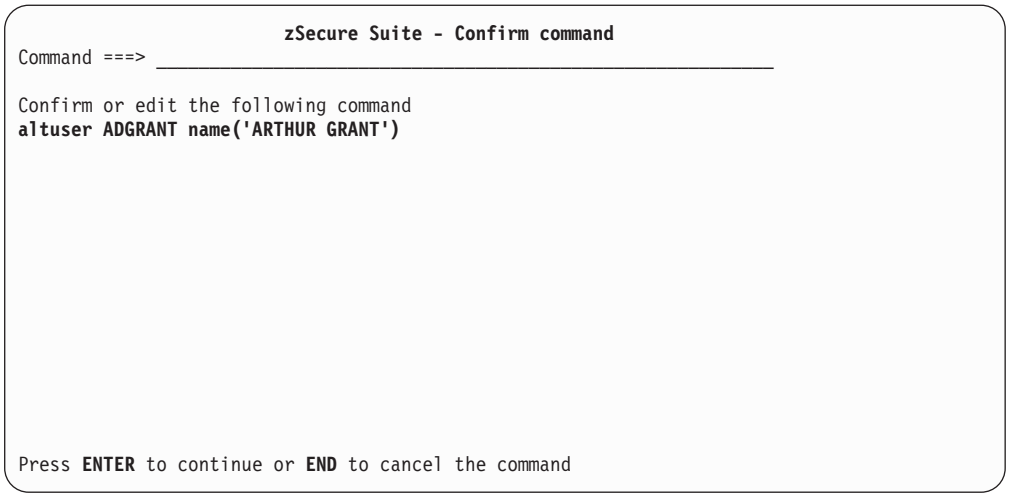

Figure 9. Confirmation Panel

Press **Enter** to accept the command. The command is not run because we specified the Queue option in SETUP CONFIRM panel. On any confirmation panel, you can cancel the command by pressing **End**, or accept it by pressing **ENTER**. You can change the circumstances in which confirmation is requested on the SETUP CONFIRM panel. ALL, the current setting is the safest option. See also "SE.4 Setup - Confirm" on page 1655.

After pressing **Enter**, the top right of the screen reads Queued in CKRCMD. This message indicates that the command you just confirmed was not run. Instead, it was stored in the CKRCMD command output file for later execution. The use of the CKRCMD file instead of direct execution of the command is another safe option set on the SETUP CONFIRM panel. If you set the **Action** parameter to EXECUTE, the command is executed immediately and not queued. The EXECUTE option is often more practical than QUEUE, but when you are learning to use Security zSecure, it is safer to queue commands rather than run them immediately.

To copy the profile, type **C** in the entry field for a profile. The USER COPY panel shown in Figure 10 on page 21 opens so you can specify a new user ID for the copy.

```
   Menu  Options  Info  Commands  Setup
--------------------------------------------------------------------------------
                        zSecure Suite - RACF - User copy
Command ===> ____________________________________________________________

_____________________________________
_  Copy permits only (target id may be a group or a user)
_  Generate RACF commands when the target user exists
_  Copy USERDATA and CUSTOMDATA
_  Specify unique segment data
_  Revoke new userid             _  Protected
_  Copy catalog aliases (only if CKFREEZE is present)
/  Issue ADDSD/RDEF for dataset and resource profiles related to the user
/  Copy RACFVARS profiles/members too
```

Figure 10. USER COPY Panel

On this panel, specify a new `userid` and password, and press ENTER. This results in the generation of the necessary RACF commands for creating the new user. These commands are added to the `CKRCMD` file. Figure 7 on page 18 is shown, with the message `Commands queued, RC=`*`rc`*. If you press END, you see the generated commands. If you press END again, you see the RESULTS panel. Press the END key again to return to the selection screen.

You are now back at the user selection screen, press ENTER to display all users again.

Now put the cursor in front of a profile (at the first column of the line command field) and press ENTER. This is equivalent to typing S in front of the profile. A *detail display* is shown with information about the single user profile you selected on the overview display. You can return to the overview display by pressing the END key. A sample detail display is shown in Figure 11 on page 22.

```

Figure 11. Detail Display

The detail display (which is a scrollable panel) also supports line commands and modifiable fields. On this panel, the line commands apply to fields within the profile, not the profile itself.

On this panel, you can experiment with modifiable fields and line commands. As long as you leave the CONFIRM settings so that you can cancel any changes, you cannot do any harm to your security database. If you type an illegal value on a field, the field is highlighted (usually in red); in this case, the RESET command can be used to reset the field to its previous value. When you are done, press END on the overview display (Figure 8 on page 19), or END twice from a detail display (Figure 11). Now, let's go and see what became of the commands written to CKRCMD.

The display in Figure 12 shows the CKRCMD file. This file is shown in an editor so you can modify, add, or delete the commands as required.

```
EDIT      GRPADM1.C2R1EF2A.CKRCMD                       Columns 00001 00072

```

Figure 13. Edited CKRCMD Output File

Make sure that the LISTUSER command is the only command left in the CKRCMD file, then press END.

You then see the RESULTS display which contains all the results from the Security zSecure run. The cursor is positioned in front of the CKRCMD line.

```
 Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                        zSecure Suite - Results  Enter R to run commands
Command ===> ____________________________________________________________

The following selections are supported:
 B Browse file               S Default action (for each file)
 E Edit file                 R Run commands
 P Print file                J Submit Job to execute commands
 V View file                 W Write file into seq. or partitioned dataset
 M E-mail report

Enter a selection in front of a highlighted line below:
 _ SYSPRINT  messages
 _ REPORT    printable reports
 _ CKRTSPRT  output from the last TSO command(s)
 _ CKRCMD    queued TSO commands
 _ CKR2PASS  queued commands for Security zSecure
 _ COMMANDS  Security zSecure input commands from last query
 _ SPFLIST   printable output from PRT primary command
 _ OPTIONS   set print options

 _ View files from recursive call (now on level 0)
```

Figure 14. Results Display

On the RESULTS display, any selectable option is highlighted. To run a command for one of the listed files, enter the command abbreviation in the entry field for the file. For example, to edit the CKRCMD file, type an **E** in the entry field for the CKRCMD file again. Then, press **Enter**.

You can also run a command saved in the CKRCMD file. Make sure that the CKRCMD file contains only the harmless LISTUSER command, type an **R** in the entry field for the CKRCMD file and press **Enter**. The LISTUSER command is run, and the result (a description of your `userid`) is displayed on the terminal.

If you press **END** on the Results panel, you return to the Security zSecure User Selection panel (Figure 7 on page 18). To reopen the Results panel, type `RESULTS` on the command line at the top of the screen.

This example shows the basic operation of Security zSecure. If you leave the `CONFIRM` option to a safe setting, and do not execute the commands generated, you can safely explore the other menu options. For more detailed examples and explanations, see the *IBM Security zSecure Admin and Audit for RACF: Getting Started Guide*.

To use the ISPF online help, place your cursor on the command line and press `PF1` to open the help panel for that panel. If you press `PF1` with the cursor in a field, a help panel opens with a description of the current field.

RESULTS - View output and results

The Results panel is displayed after a run if any of the files CKREPORT, CKRCMD, or CKR2PASS contains program output. It can be called up at any time using the `RESULTS` primary command.

The options that can be used are highlighted on the menu. For example, to browse the TSO commands, type a **B** in front of CKRCMD. If the program generated second-pass commands, these are stored in CKR2PASS. Type **R** in the input field in front of the CKR2PASS entry to run the commands.

Use this panel to edit, browse, or run the indicated files.

```
   Menu   Options   Info   Commands   Setup
 ------------------------------------------------------------------------------

                          zSecure - Results  Enter R to run commands
Command ===> ____________________________________________________________

The following selections are supported:
  B Browse file               S Default action (for each file)
  E Edit file                 R Run commands
  P Print file                J Submit Job to execute commands
  V View file                 W Write file into seq. or partitioned dataset
  M E-mail report

Enter a selection in front of a highlighted line below:
_ SYSPRINT  messages
_ REPORT    printable reports
_ CKRTSPRT  output from the last TSO command(s)
_ CKRCMD    queued TSO commands
_ CKR2PASS  queued commands for Security zSecure
_ COMMANDS  Security zSecure input commands from last query
_ SPFLIST   printable output from PRT primary command
_ OPTIONS   set print options
```

Figure 15. Results Display - Available options

Valid selections are described in the following table.

Table 4. Results Display - commands available

Command	Action
B	Browse the file
E	Edit the file
G	Same as R
J	Submit a batch job to run the commands in the file
M	Email the file
P	Print the file, using the print options determined by the OPTIONS menu
R	Run the commands in the file
S	Default action. The default is different for each file.
V	View the file
W	Write the file into a (sequential or partitioned) data set

SYSPRINT
This file contains messages describing the results, and any errors, from the last program run. Messages generated by `VERIFY` commands, and output from the `SHOW` command is also written to this file. Valid selections for this file are `S`, `B`, `E`, `P`, `V`, `M`, and `W`. The default action is browse.

REPORT
This file contains output from queries in Print Format. Valid selections for this file are `S`, `B`, `E`, `P`, `V`, `M`, and `W`. The default action is browse.

CKRTSPRT
This file contains output from the last TSO commands. Valid selections for this file are `S`, `B`, `E`, `P`, `V`, `M`, and `W`. The default action is browse.

CKRCMD
If the command action is set to `QUEUE`, this file contains `TSO` commands

generated by , VERIFY, COPY, MOVE, and REMOVE commands, as well as commands generated by line commands or modified fields. This can include RACF, CKGRACF, and IDCAMS commands. This release does not yet support generating ACF2 commands. Valid selections for this file are S, B, E, P, V, M, W, R, or G. The default action is edit.

All commands generated in one run are **added** only to the CKRCMD file. The file is emptied only when a new initial query is performed.

You can edit and run only the commands from the lowest level of the query **not** from recursive calls to Security zSecure. An error message is generated if you try to run or edit the file from the wrong level.

If you selected multiple complexes, multiple CKRCMD files are used. When you select the CKRCMD file, an extra selection panel opens like the one shown in Figure 16.

```
 Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                          zSecure Suite - Results  Use END for other files
COMMAND ===>                                                 Scroll ===> CSR

The following selections are supported:
 B Browse file               S Default action (for each file)
 E Edit file                 R Run commands
 P Print file                J Submit Job to execute commands
 V View file                 W Write file into seq. or partitioned dataset
 M E-mail report

CKRCMD for the specified environments:

     Complex  Njenode   Rrsfnode   System     zSecNode #Lines
   _ DINO     JES2DINO  DINO       DINO       ?        2
   _ CNRLPROG C##4      C##4       C##4       ?        1
****************************** Bottom of data ********************************
```

Figure 16. Results Display - CKRCMD file

All actions specified are performed only on the selected CKRCMD.

CKR2PASS
This file contains IBM Security zSecure commands generated by line commands on profiles. These commands are always queued, and can be executed by typing **R** or **J** in the selection field for **CKR2PASS**. Valid selections for this file are S, B, E, P, V, M, W, R, or G. The default action is edit.

COMMANDS
This file contains the input commands from the last run of the program. Valid selections for this file are E, S, M, and /. Use the E, S, and / actions to edit the commands. You can change, run, or submit the commands or save them to a private data set.

SPFLIST
The ISPF LIST data set contains printable output generated by the program when the PRT command was issued on a display. Valid selections for this file are M, S and /. The S and / actions lead to the ISPF List panel.

OPTIONS
Set print options. Valid selections for this file are S and /. Both actions lead to the Print Options panel.

Recursive calls

From a record display, it is often possible to invoke another, more detailed record display. This action is known as a recursive call. Any commands queued by recursive calls are saved in the same CKRCMD file. These commands can be executed when you leave the initial display. You can view the SYSPRINT output from a recursive call by issuing the SYSPREV primary command or through the Results panel by selecting one of the files listed at the bottom of the panel.

```
  Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                          zSecure Suite - Results
Command ===> ____________________________________________________________

The following selections are supported:
 B Browse file                S Default action (for each file)
 E Edit file                  R Run commands
 P Print file                 J Submit Job to execute commands
 V View file                  W Write file into seq. or partitioned dataset
 M E-mail report

Enter a selection in front of a highlighted line below:
_  SYSPRINT  messages
_  REPORT    printable reports
_  CKRTSPRT  output from the last TSO  command(s)
_  CKRCMD    queued TSO commands
_  CKR2PASS  queued commands for Security zSecure
_  COMMANDS  Security zSecure input commands from last query
_  SPFLIST   printable output from PRT primary command
_  OPTIONS   set print options

_   View files from recursive call (now on level 0)
```

Figure 17. Results Display - Recursive calls

CKRCMD - Viewing and executing commands

When selecting a CKRCMD file you are presented with the standard ISPF editor, with the file loaded.

```

Figure 20. RACF command routing panel

Figure 20 displays the available command routing destinations or nodes. There are three types of nodes:

RRSF
Nodes are defined by RACF. RACF commands only are directed via the AT or ONLYAT parameter.

ZSEC
Nodes are defined by zSecure Server. The local zSecure server will transmit the commands to the remote system. On the remote system, commands are executed by the remote zSecure server.

NJE
Nodes are defined by JES2. The commands are executed using a batch job which is routed to the remote system.

Each row in Figure 20 represents a single system unless multiple nodes of the same type exist for a single system. The system name and system ID are displayed in columns **Sysname** and **SID**. The RRSF, ZSEC and NJE node names are displayed in the **RRSFNode**, **zSecNode**, and **NJENode** columns.

One node can be chosen from each row using the L, A, O, Z or J selection characters.

Selection character	Description
L	Route command to the local system.
A	Route command to the RRSFNode using the RRSF AT() parameter.
O	Route command to the RRSFNode using the RRSF ONLAT() parameter.
Z	Route command to the zSecNode.
J	Route command to the NJENode.

RRSF routing is implemented by appending the AT() or ONLYAT() parameters to the command. Only RACF commands will be able to be routed using RRSF. The command is issued locally and RACF performs the routing. The **Userid** column indicates the userid that is used for the RRSF AT() and ONLYAT() parameters.

The **A**, **O**, **Z**, and **J** columns in the preceding table indicate what particular routing method is available.

The **L** column displays a character to indicate when a row is considered to be the local or normal node.

=	This is the local node. The command is directed here if you select **Local only** for the Command Routing selection on the "SE.4 Setup - Confirm" on page 1655 panel.
>	This is the normal node. The command is directed here if you select **Normal** for the Command Routing selection on the "SE.4 Setup - Confirm" on page 1655 panel.
*	This node is both local and normal.

Access list display modes - reference material

This section describes more advanced zSecure options that you might want to skip until you have mastered basic operation of IBM Security zSecure.

When RACF shows an access list, it only shows the RACF IDs and access levels. Finding out the access each user has can be difficult if the user is connected to many groups. Security zSecure can display the access list in the following ways so you can investigate each user access: *exploded*, *resolved*, *effective*, and *trust*. In addition, you can further customize the access lists using the `SCOPE` and `NOSCOPE` and the `UNIVERSAL` and `NOUNIVERSAL` commands.

The display mode can be changed interactively with the `ACL` command or specified as an output modifier.

An *exploded* access list shows every way in which a user has access to a profile. All group access list entries are expanded by entries for each user in the group. If a user is connected to multiple groups on the access list, the `userid` is shown multiple times. Access due to a group-operations or operations attribute is shown as well. In addition, administrative access through group-special or ownership is shown as `OWNER` and administrative access through a High-level qualifier is displayed as `QUALOWN`. You can remove this access information from the view by issuing a `NOSCOPE`. You can also sort the access list to view access by level, group, or userid. An exploded access list is especially helpful if you want to remove a user or group from an access list and you are unsure how many ways that access is granted.

A *resolved* access list shows the actual access that a user has to a profile. If a user is on the access list, that entry is displayed. If a user is not on the access list but some of the connect groups for the user are on the access list, the *highest* access that the user has through any of the connect groups is displayed. Administrative authority can be taken into account by using the *scope* toggle. In that case, administrative access is considered higher than normal access through the access list.

An *effective* access lists shows the effective access that a user has to a profile. The effective access list is the resolved access list extended with entries for users that are not explicitly on the access list but have access due to a group operations or operations attribute, these show the access level ALTER-O and the group concerned, or `- oper -`, respectively. Administrative authority can be taken into account by using the *scope* toggle. In that case, administrative access is considered higher than normal access through the access list.

A *trust* access list shows the actual access that a user has to a profile, as well as the administrative access. It shows all ways in which the user currently has data access. In addition to this data access, administrative authority through group-special or ownership is displayed as OWNER and administrative access through a High-level qualifier is displayed as QUALOWN. The trust access list shows exactly the trust relations that are considered for the TRUSTED report types if the profile protects a sensitive resource.

The effect of the SCOPE and NOSCOPE toggle is visible for all except normal access lists. SCOPE shows administrative access through group-special or ownership as OWNER and administrative access through a High-level qualifier as QUALOWN, NOSCOPE eliminates the administrative access. The default effect is NOSCOPE for output modifiers EXPLODE, RESOLVE, and EFFECTIVE, as well as for ISPF ACL commands ACL NORMAL, ACL RESOLVE, and ACL EFFECTIVE. The default is SCOPE for the ISPF ACL commands ACL EXPLODE and ACL TRUST.

The effect of the UNIVERSAL and NOUNIVERSAL toggle is the same for all types of access list. If UNIVERSAL is specified default connections to universal groups–that is, connections with USE authority and no group special, operations, or auditor attributes–are taken into account, as well as the access granted by system-wide operations, if applicable to the type of access list shown. If NOUNIVERSAL is specified neither default connects to universal groups nor system-wide operations users are included in the access list.

The following tables show examples of exploded and resolved access lists. It uses five users (USER1, USER2, USER3, USER4, and USER5) and two groups. GROUP12 consists of USER1 and USER2. GROUP234 consists of USER2, USER3, and USER4. The following table shows the actual access list. All the following examples assume that the UNIVERSAL and NOUNIVERSAL toggle is set to UNIVERSAL.

The normal access list as displayed after an ACL NORMAL command which sets the scope attribute to NOSCOPE.

Table 5. Normal Access List

User	Access	Access List id
USER1	READ	USER1
USER2	UPDATE	USER2
USER3	NONE	USER3
-group-	CONTROL	GROUP12
-group-	READ	GROUP234

The following table shows the exploded access list as it would be after an ACL EXPLODE command. An ACL EXPLODE command turns on SCOPE automatically. It shows every way the user might have access. Note that the groups are no longer included in the leftmost column.

Table 6. Exploded Access List (EXPLODE, SCOPE modifiers or ACL EXPLODE)

User	Access	Access List id
USER1	OWNER	USER1
USER1	CONTROL	GROUP12
USER1	READ	USER1
USER2	CONTROL	GROUP12

Table 6. Exploded Access List (EXPLODE, SCOPE modifiers or ACL EXPLODE) (continued)

User	Access	Access List id
USER2	UPDATE	USER2
USER2	READ	GROUP234
USER3	READ	GROUP234
USER3	NONE	USER3
USER4	READ	GROUP234
USER4	ALTER-O	- oper -
USER5	ALTER-O	- oper -

The Resolved Access List table shows the actual way the user has access when using the `RESOLVE` modifier or the ISPF command `ACL RESOLVE`. A user ID on the access list overrides any group access. If several group accesses are included, the highest is used.

Table 7. Resolved Access List (RESOLVE modifier or ACL RESOLVE)

User	Access	Access List id
USER1	READ	USER1
USER2	UPDATE	USER2
USER3	NONE	USER3
USER4	READ	GROUP234

The Effective Access List table is like the Resolved access list with the exception that system-wide operations and group-operations are taken into account.

Table 8. Effective Access List (EFFECTIVE modifier or ACL EFFECTIVE)

User	Access	Access List id
USER1	READ	USER1
USER2	UPDATE	USER2
USER3	NONE	USER3
USER4	READ	GROUP234
USER5	ALTER-O	- oper -

Table 9 shows the resolved access list with scope activated, as it would be when changing from explode to resolve):

Table 9. Resolved Access List with scope (RESOLVE, SCOPE modifiers or ACL RESOLVE SCOPE)

User	Access	Access List id
USER1	OWNER	USER1
USER2	UPDATE	USER2
USER3	NONE	USER3
USER4	READ	GROUP234

Table 10. Effective Access List with scope (EFFECTIVE, SCOPE modifiers or ACL EFFECTIVE SCOPE)

User	Access	Access List id
USER1	OWNER	USER1
USER1	READ	USER1
USER2	UPDATE	USER2
USER3	NONE	USER3
USER4	READ	GROUP234
USER5	ALTER-O	- oper -

Table 11. Exploded Access List without scope (EXPLODE modifier or ACL EXPLODE NOSCOPE)

User	Access	Access List id
USER1	CONTROL	GROUP12
USER1	READ	USER1
USER2	CONTROL	GROUP12
USER2	UPDATE	USER2
USER2	READ	GROUP234
USER3	READ	GROUP234
USER3	NONE	USER3
USER4	READ	GROUP234
USER4	ALTER-O	- oper -
USER5	ALTER-O	- oper -

Table 12. Trust Access List (ACL TRUST)

User	Access	Access List id
USER1	OWNER	USER1
USER1	CONTROL	GROUP12
USER1	READ	USER1
USER2	CONTROL	GROUP12
USER2	UPDATE	USER2
USER2	READ	GROUP234
USER3	READ	GROUP234
USER3	NONE	USER3
USER4	READ	GROUP234
USER5	ALTER-O	- oper -

An access list can be sorted in three ways:

1. by access level (from ALTER to NONE
2. by userid
3. by access list id (that is, the id on the access list, not the resolved or exploded userid).

In the examples, the access list is sorted by user ID. The ACL display format shown is determined by the combination of the sort order and the access list format, which are independent settings.

The default access list layout can be set on the Setup View Panel (Figure 550 on page 1660) and using the SET primary command. On a display like the User or Data set overview display that has an access list or a connect overview, the layout can also be changed using one of the following ACL primary commands.

ACL NORMAL, or ASIS
Shows the actual access list. That is, the list is not exploded, resolved, or effective with no administrative authorities regardless of whether you add SCOPE or NOSCOPE to the command.

ACL RESOLVE
Shows a resolved access list. It omits administrative authorities unless you add SCOPE to the command.

ACL EXPLODE
Shows an exploded access list. It adds administrative authorities unless you add NOSCOPE to the command.

ACL EFFECTIVE
Shows an effective access list. It omits administrative authorities unless you add SCOPE to the command.

ACL TRUST
Shows the trust relations of the profile. This command shows all ways in which the user currently has data access as well as administrative access. These access entries are the same as the trust relations that are considered for the TRUSTED report types if the profile protects a sensitive resource.

ACL SCOPE
Activates display of administrative authorities as part of the access list display. This command includes group-special authority, and ownership authority through owner and High-level qualifiers. The command is honored only if the access list is not displayed in ACL NORMAL mode.

ACL NOSCOPE
Deactivates display of administrative authorities as part of the access list display.

ACL SORT ID
Sort access list by id

ACL SORT USER
Sort access list by user (with resolve/explode)

ACL SORT ACCESS
Sort access list from OWNER to NONE

ACL UNIVERSAL
Takes system-wide operations and users with a default connection to a universal group into consideration when building the access list. It has no effect on the current SCOPE or NOSCOPE and NORMAL, EXPLODE, RESOLVE or EFFECTIVE settings. The command is refused if only a part of the RACF database has been read.

ACL NOUNIVERSAL
This deactivates the UNIVERSAL option. It has no effect on the current SCOPE or NOSCOPE and NORMAL, EXPLODE, RESOLVE or EFFECTIVE settings.

You can use abbreviations for the ACL commands. For example, you can issue the command `ACL S AC` for `ACL SORT ACCESS`.

If you want to change an access list by typing over the values in the fields, the access list must be in normal mode, `ACL NORMAL` , for example). It can be in any sort order.

IN INFORMATION - Information and documentation

The INFORMATION menu option **IN.M** provides access to an online version of the *IBM Security zSecure: Messages Guide* in IBM BookManager format. This guide provides information about all the messages that can be issued by different IBM Security zSecure products. You can also access the *IBM Security zSecure: Messages Guide* and other zSecure documentation online. For more detailed information, see "Accessing publications online" on page xvi.

For more information about RACF administration and commands, you can refer to the following IBM RACF manuals listed.

- z/OS Security Server (RACF) **Command Language Reference** (SA22-7687) This manual describes all RACF commands, parameters, and options in detail.
- z/OS Security Server (RACF) **Security Administrator's Guide** (SA22-7683) This manual is the primary reference for RACF system and group administrators.

LO LOCAL - Locally defined options

Use the LOCAL option to create customized versions of the IBM Security zSecure panels or to add new functionality to the product. This option is designed to be used by personnel who are experienced in writing ISPF dialogues. For details on using this option see the section on locally defined functions in the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

FIELDS - Show CARLa fields available

The primary command FIELDS shows the field names defined in zSecure, as well as those defined in the RACF templates, together with the default properties assigned by zSecure.

You can use the first display that is shown to select either the built-in fields of the product or the fields imported from RACF.

```
zSecure Display Selection                          1 s elapsed, 0.4 s CPU
Command ===> ____________________________________________________ Scroll===> CSR

  Name     Summary Records Title
s BUILTIN       52    2490 Builtin field definitions by newlist type
_ TEMPLATE       1     451 RACF template definitions
****************************** Bottom of Data ********************************
```

Figure 21. Display Selection panel

After selecting the *built-in* fields, a panel is displayed showing all `NEWLIST` types for which *built-in* fields have been defined as shown in Figure 22 on page 36. To view the fields defined for a `NEWLIST`, type a `/` in the entry field for the `NEWLIST` type entry, then press **Enter**. A detail panel opens with a listing of the fields defined for the `NEWLIST` as shown in Figure 22 on page 36.

Figure 23. Field summary - overview display

Table 14 describes the columns available on the FIELD summary panel. You must scroll the display to the right to view some of the fields.

Table 14. Field summary for NEWLIST type **built-in** *field*

Field name	Description
Field	The name of the field.
Description	A short (29 char) description of the field function.
Len	Default output length.
Format	Default output format.
Rpt	Indicates if this field can contain multiple values for one record.
Mod	Indicates if this field can be modified on a display.
Id	Numerical field identifier.
Help pnl	The help panel associated with this field.
Hor	Indicates if the field has the HORIZONTAL modifier by default.
Wrp	Indicates if the field has the WRAP modifier by default.
Lwr	For modifiable fields, this field indicates if mixed case input is accepted. For non-modifiable fields, the field is empty. Modifiable fields are only available with a zSecure Admin entitlement.
SubSelct	Shows the names of the repeated fields that can be used with this field in subselect processing.
Restrictions	This shows the authority that a user needs to see this field when running in restricted mode.
Header	The default header.

When you select one of the fields on this display you are shown the following detail panel. This panel contains the same information, but it is shown in a more expansive format.

XML support within IBM Security zSecure

XML has become the standard for cross-platform and intersystem communication. IBM Security zSecure can transform your system data, security controls, and event (SMF) reports to make the best use of XML for your applications.

First some definitions:

XML (eXtensible Markup Language)
A language composed of labels and values. The values are grouped in a context and can be represented as a tree.

DTD (Document Type Definition)
The syntactic definition of the XML document, which is used to determine the validity of the document. The DTD contains a basic description of each element by describing its general format, identifying its possible attributes, and detailing its repeatability. The DTD can be internal to the document or externally referenced.

XSLT (eXtensible Stylesheet Language Transformations)
A standardized XML-based collection of commands, also called a vocabulary or markup language, to transform the content and data stored within an XML document into a different form. An XSLT is referenced within the document that is to be transformed. zSecure provides a default stylesheet zSecure provides a sample XSLT stylesheet available at http://publib.boulder.ibm.com/infocenter/tivihelp/v2r1/topic/com.ibm.zsecure.doc_1.13/c2rxsl01.xsl. For details, see "The XML_STYLESHEET parameter" on page 41.

An XML document is a file or data set with tags defining its content but not its format. This separation between content and format means that the same document can be processed with different XSLT styles sheets to produce different output. For example, an XML document can be processed against one XSLT

stylesheet and produce an HTML file for display by a browser. That same XML document processed against a different XSLT stylesheet can produce a differently formatted report suited for display on a wireless device, and a third stylesheet might produce input appropriate for Microsoft Excel. There is no limit to the number of layouts that can be produced by the same XML document by applying different XSLT files. The real power of this becomes apparent with the realization that, because the data (XML document) is independent of the format (XSLT file), the input files can change, but as long as the document conforms to the DTD, it can be transformed by any XSLT file utilizing the DTD for the document.

These three files (XML, DTD, and XSLT) work together to produce a self-documenting database system readable by any platform or system recognizing XML. There are no proprietary data formats, as there are with most contemporary database systems. This means that any machine based (or human based) process can read and understand the basics of the data.

There is a fourth piece of the report output which is specific to zSecure. It is a data dictionary which, if requested, is embedded within the generated document and assists the XSLT in formatting the XML document. The data dictionary is required for any XML reports requesting the default XSLT be used to format the output. The data dictionary is optional if the default XSLT is not used.

Although XML is generally used for B2B processes, it can also be used within an enterprise. For example, an zSecure XML report can be routed to a browser for display, or it can be viewed by other programs such as Microsoft Excel and other XML services using the XSLT to transform the data.

Starting with IBM Security zSecure

zSecure produces XML output instead of the usual text output by changing a few options in the zSecure program requesting the report.

The first step is specifying `FILEOPTION FILEFORMAT=XML`. By this specification, several new rules come into play:

1. The `NEWLIST` statements must be named because these names are used as an `ELEMENT` in the XML document. Names must conform to both zSecure and XML standards.
2. There must be no duplication of field names in a `LIST` statement with the ddname, `NEWLIST`, and `MERGELIST` names. This requirement makes each of these entries unique and avoids confusion.
3. The implementation used for XML rules in zSecure also requires that field names be unique within a `LIST` statement. Users cannot display or report the same field more than once per `LIST` statement. However, if there is a need to do so, users could use a `DEFINE` statement to provide the field with a different name.
4. Ensure that the output file is not used by any other (non-XML) support functions. Do not reference the file before the `FILEOPTION` command that indicates its use as an XML file.
5. All field names, `NEWLIST` names, and ddnames must use the following conventions:
   a. Contain only alphabetic or numeric characters, underscores, or hyphens, and no national characters (#$@).
   b. Begin with an alphabetic, but not the character string: XML.

The ddnames have an additional limitation: The names must not contain hyphens or underscores.

In its simplest form, the data report contains only one element per NEWLIST statement. Without any additional parameters the output is the header and values, as shown in Figure 25. Most applications generate more comprehensive reports with many more entries. To display these reports, it is probably best to use XSLT to transform the document.

By default, an inline DTD is included in the output. If NOXML_DTD or an imbedded XSLT stylesheet is requested, the DTD is suppressed. Using a DTD provides a self-documenting XML document and enables XML parsers to validate the document.

Without an XSLT to tell the using program how to format the document, web browsers, Excel and other programs are able to parse the XML document in a simple layout, without any special formatting. You must allocate an output dataset to MYXML before running this sample report in batch or ISPF.

```
fileoption  dd=myxml fileformat=xml
newlist dd=myxml type=system name=SYS
sortlist system mvslvl
```

```
<?xml version="1.0" encoding="IBM1047"?>
<!DOCTYPE MYXML [

<SYSTEM>DEMO</SYSTEM>
<MVSLVL>SP7.0.4</MVSLVL>
</SYS>
</MYXML>
```

Figure 25. Two cells in table: zSecure input - XML text output when browsed (via ISPF) on the mainframe

Use XSLT and the data dictionary to format the output

The power of XML becomes more apparent with the zSecure option to generate a processing instruction to use an XSLT stylesheet.

The XSLT supplied with zSecure produces a tabular report that can be used by web browsers, Microsoft Excel, and other such programs. However, if you want different formatting, you can define and apply your own XSLT.

After specifying two additional FILEOPTION parameters: XML_STYLESHEET and XML_DATADICT, the example document grows to 309 lines. This is because the new document includes the zSecure default XSLT stylesheet together with the data dictionary. The data dictionary is required only when using the default stylesheet provided with zSecure.

The data dictionary is valuable as it provides information about the report title, top title, and subtitle as well as vital formatting information for each field in the report. This information is used by the stylesheet to format the report as seen in Figure 26 on page 41.

Figure 26 also illustrates how to output the XML document into an existing z/OS data set using the XML_DATADICT parameter. This option is useful if the document is to be used in a zSeries® processing environment.

```
alloc dd=myxml dsn=user1.output.xml type=output
fileoption dd=myxml encoding=EBCDIC fileformat=xml xml_datadict,
       xml_stylesheet=imbed(m=c2rxsl01)
newlist dd=myxml type=system name=SYS
 list system mvslvl
```

```
0001 <?xml version="1.0" encoding="IBM1047"?>
0002 <?xml-stylesheet type="text/xsl" href="#"?>
0003 <xsl:stylesheet id="C2RXSL01" version="1.0"
0004     xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
. . .
0299 <field name="MVSLVL" format="" width="8" align="left">
0300 <header>MVS</header><description>MVS level</description>
0301 </field>
0302 </report>
0303 </datadict>
0304 <SYS>
0305 <SYSTEM>DEMO</SYSTEM>
0306 <MVSLVL>SP7.0.4</MVSLVL>
0307 </SYS>
0308 </zAudit:MYXML>
0309 </xsl:stylesheet>
```

Figure 26. Two cells in table: zSecure input - XML text output. Note that lines 299-301 show the result of specifying the XML_DATADICT parameter

If you change the `dsn=user1.output.xml` option to a fully qualified z/OS Unix path, the output can be routed to a file in your HFS or zFS file system. The z/OS UNIX file is created if it is not present when needed. However, the directory path must exist. The code for this example is shown in Figure 27.

```
alloc dd=myxml type=output path='/u/user1/work.xml'
fileoption dd=myxml fileformat=xml xml_datadict,
       xml_stylesheet=imbed(m=c2rxsl01)
newlist dd=myxml type=system name=SYS
 sortlist system mvslvl
```

Figure 27. Outputting XML to z/OS Unix file

The XML_STYLESHEET parameter

The XML_STYLESHEET parameter allows different style sheets to be specified, providing maximum flexibility. You can request that it be included within the document by specifying `XML_STYLESHEET=IMBED(optional_ddname,membername)`. As previously seen in Figure 26, this parameter increases the size of the document. Instead, it can be preferable to specify the location of the stylesheet using the `URI` parameter. The `URI` parameter accepts the standard Uniform Resource Identifier for the stylesheet specification, for example http://publib.boulder.ibm.com/infocenter/tivihelp/v2r1/topic/com.ibm.zsecure.doc_1.13/c2rxsl01.xsl. When the stylesheet is specified by `URI` parameter, the stylesheet is not embedded which makes the document much smaller. However, the `URI` option does require that the user have access to the resource referenced in the URI.

The `IMBED` option enables a local style sheet while the `URI` enables the installation to use a centralized production stylesheet. The local option is useful to develop and test the stylesheet in a test environment, and the `URI` option is useful for using proven stylesheets in the production environment. You can also specify the `URI` option for internal users that have access to the file or data set specified by the `URI` file/data set), and use the `IMBED` option for shipping to external users where it is not practical to provide public access to a `URI` file or data set. Alternatively, you

might want to have test and production versions within the IMBED or URI parameters as well.

```
alloc dd=myxml dsn=crmbmh1.output.xml type=output
fileoption dd=myxml  fileformat=xml xml_datadict,
  xml_stylesheet=URI('http://publib.boulder.ibm.com/infocenter/
                     tivihelp/v2r1/topic/com.ibm.zsecure.doc_1.12/c2rxsl01.xsl')
newlist dd=myxml type=system name=SYS
 sortlist system mvslvl
```

Figure 28. Use of the URI= parameter for the stylesheet specification

The power and flexibility provided by these parameters is important.

1. By having the DTD included within the document, validating the document is easier, and changes to the report do not cause invalid documents to be created. The document is also self documenting since it carries its own basic definitions.
2. Using the default stylesheet makes it effortless to produce tabular format reports that can be viewed by programs that process HTML documents.
3. Total flexibility with regards to the stylesheet specification makes it simple for an installation to tailor and use a customized stylesheet with minimal effort. The only requirement is to change the URI value or specify the IMBED parameter.

Output Processing

Output preparation is also important. XML output lines can be longer than most people expect. Ensure that your mainframe output file is defined with RECFM=VB and a large LRECL. For example, LRECL=255 is an acceptable value for testing, but for production use, a larger number, such as 1024 is preferable. As shown in Figure 27 on page 41, z/OS Unix files in your HFS or zFS file systems are also appropriate destinations for your XML reports.

Optimal encoding of your output differs by the system on which it is processed. By omitting the ENCODING parameter on the FILEOPTION statement, it defaults to EBCDIC, which is appropriate for mainframe usage. However, if you plan to display the output on a PC, we recommend that you specify ENCODING=UTF-8 (Unicode). If you transfer a mainframe formatted XML document to the PC, the ENCODING parameter value can cause parsers to issue a diagnostic error. To prevent this problem, remove or replace the encoding="IBM1047" with the proper encoding value.

zSecure runs on zSeries mainframes, but there are many means of distributing the resulting output. In addition to the traditional FTP mechanisms, zSecure offers a few options within itself. The output can also be routed through the zSecure email interface, once it has been set up, when coupled with the OUTPUTFORMAT=ATTACH parameter.

```
fileoption dd=c2remail fileformat=xml xml_datadict,
       xml_stylesheet=imbed(m=c2rxsl01) encoding=utf-8
option dd=c2remail mailto=user1@company.com,
       from=user2@company.com  outputformat=attach
newlist dd=c2remail type=system name=SYS
 sortlist system mvslvl
```

Figure 29. Configuring the zSecure request to email the output as an attachment

After the zSecure program in Figure 29 runs (either batch or ISPF), the email is sent with the attached file. Remember that other email options, such as REPLYTO=, are also available for your use.

Attaching documents adds another powerful feature to the zSecure XML support: You can email the report document from the mainframe to the recipients. Then, they can review the file using the program of their choice, at their convenience.

If you decide to transfer the XML file from the mainframe to a PC using FTP or another such transport mechanism, remember to consider the file encoding. If the report was originally produced with no `ENCODING` or `ENCODING=EBCDIC`, it must be transferred as a CHAR operation. However, if the report was produced with the PC in mind, with `ENCODING=UTF-8`, it must be transferred as a BINARY operation. Normally, UTF-8 data is not displayable on the mainframe without UNICODE processing. One other caveat, converting EBCDIC to ASCII (as in a CHAR transfer) cannot handle the '[' and ']' characters in XML properly.

SUMMARY Reports and XML

When the default XSLT is applied to the zSecure SUMMARY reports they are formatted just like the printed zSecure report. The SUMMARY report produces rows of output, omitting the repeated values of the leftmost fields and providing values for the fields on the rest of the row.

The sample program in Figure 29 on page 42 runs on the mainframe and e-mails the output to the specified user who then can review the output using Notepad, a web browser, Microsoft Excel, or another XML formatting program. For samples of the program and output, see the following figures.

```
fileoption dd=c2remail fileformat=xml xml_datadict,
       xml_stylesheet=imbed(m=c2rxsl01) encoding=utf-8
option dd=c2remail mailto=user2@company.com,
       from=user1@company.com outputformat=attach
newlist dd=c2remail type=smf name=allomvs
 select event=allomvs
 summary userid * event
```

XML-proofing zSecure reports

You can produce XML output from some of the existing (tabular output) sample zSecure reports by adding the necessary XML parameters to the OPTION, FILEOPTION, or NEWLIST commands before the INCLUDE command which imbeds the report program. Other zSecure reports produce formatted reports with inserted text or output which is not in tabular format, or they produce ISPF displays. These reports do not work if an attempt is made to convert their output to XML. The WRAP formatting option is also not available when the output is going to XML.

Finally, as you adapt your existing zSecure reports to the XML capability, remember to observe the requirements detailed in Section "Starting with IBM Security zSecure" on page 39.

Summary

XML output provides reports that can be utilized in multiple fashions using XSLT. zSecure provides XML output when the proper output parameters are specified. The DTD is generated by default, unless the `XML_STYLESHEET=(IMBED(membername))` option is specified. `XML_DATADICT` is required if the IBM-supplied default XSLT is specified.

Names of fields, `NEWLIST` types, and ddnames have limitations and must contain only alphabetic and numeric characters, underscores, or hyphens. National characters (`#$@`)) are not supported. The value must begin with an alphabetic character but not the string XML. The ddnames cannot contain hyphens and underscores.

Ensure the z/OS output data set is allocated with VB record format and a large LRECL (for example 1024). The default encoding is `EBCDIC` for mainframe usage

and UTF-8 for PC usage. This default is used if the ENCODING= parameter is omitted. Use of email services can simplify transfer to PCs by using the email operands and OUTPUTFORMAT=ATTACH.

Output formatting can use the IBM-supplied default or an installation-defined XSLT. The XSLT can be embedded or referenced by web address in the URI parameter.

Conclusion

zSecure supports the generation of XML documents from system data. These documents can be transformed to commonly used formats such as Microsoft Excel and other formats to meet the needs of the organization and users. This functionality is provided in addition to zSecure support for generate letters from the information provided in SMF event reports and security database fields. With the XML support, zSecure can use different style sheets to provide the security administration and auditing information from a single XML report in multiple output formats and for viewing on multiple output devices such as cell phone, pagers, and email.

Compare processing

Use compare processing to detect and report on changes in selected fields by comparing the values in a designated baseline CKFREEZE data set against another CKFREEZE data set.

For an example of how the compare process is used, see the *IBM Security zSecure Alert: User Reference Manual* for information about the zSecure Alert extended monitoring function. This function performs a comparison that monitors system settings and reports changes using the Alert messaging function.

You can set up your own compare process using the CARLa language statements and options for compare processing. The comparison process is described in "Setting up and running a comparison."

Setting up and running a comparison

Use the COMPAREOPT statement to define a set of comparison properties for any NEWLIST that references it using the COMPAREOPT=name option.

Figure 35 on page 47 provides an overview of setting up and processing a comparison. To understand the process description that follows the diagram, review the following terms.

COMPARE_CHANGES
Defined variable type for listing the differences in the fields that are compared. See "Defining variables for comparison results (COMPAREOPT)" on page 754.

COMPARE_RESULT
Defined variable type for returning a value that describes the outcome of the compare process. For example, if the compare results show a new item, ADD is returned. If a value has been modified, the value CHG+ is returned. See "Defining variables for comparison results (COMPAREOPT)" on page 754.

COMPAREOPT
The CARLa statement that specifies the compare options which determine what to compare.

BY=
Specifies the value for the key used in the comparison process to determine the set of records to be compared. This parameter is specified in the `COMPAREOPT` statement.

BASE=
Specifies the condition that designates the baseline record in the set specified using the `BY=` parameter.

COMPARE=
Determines the list of fields to be compared. This parameter is specified in the `COMPAREOPT` statement.

SHOW=
Determines which of the compared records to include in the output based on the `COMPARE_RESULT` value returned. This parameter is specified in the `COMPAREOPT` statement.

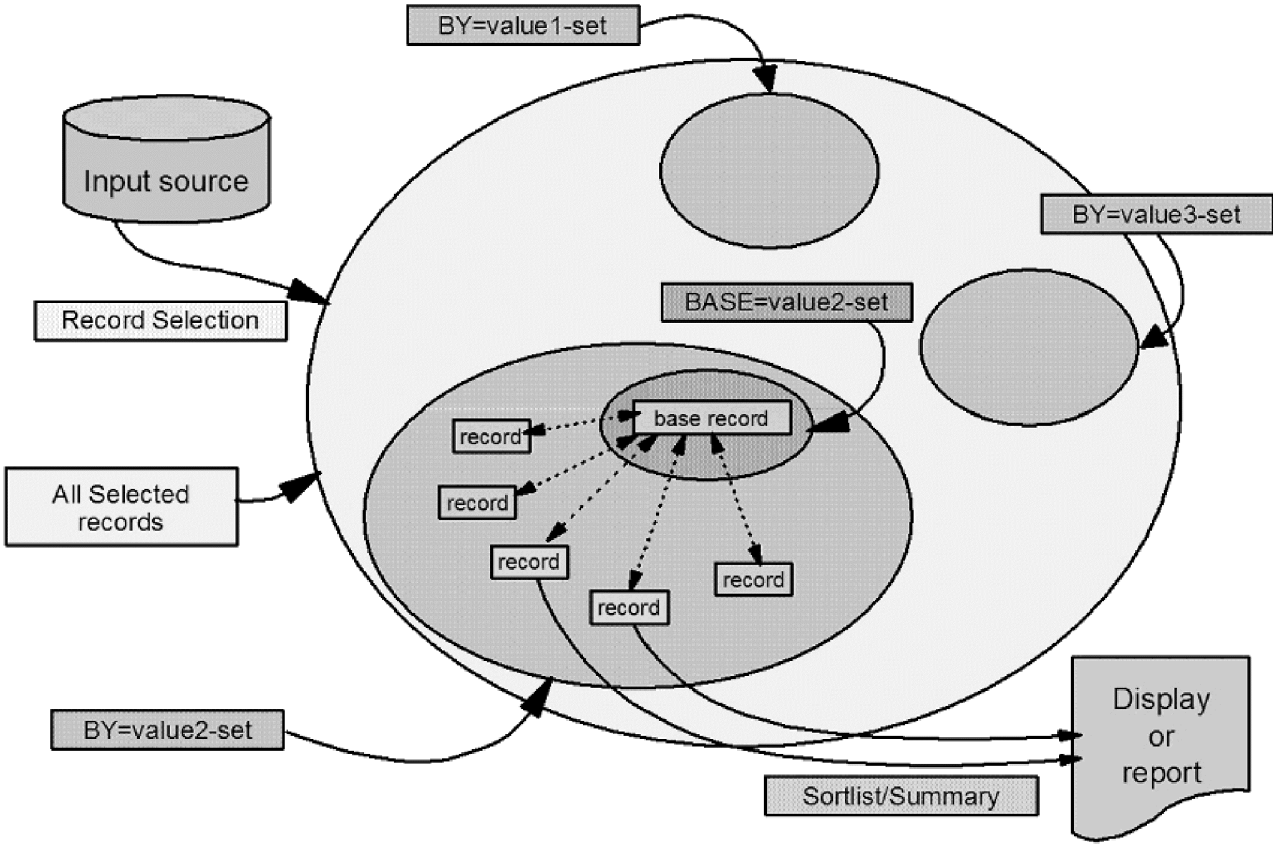

Figure 35. Compare processing conceptual diagram

When compare processing is activated, the `CKRCARLA` program uses the standard select and exclude processing to read the required data from the applicable input source. The read operation creates an in-memory data structure representing the input data. In the process diagram, this structure is shown as *All Selected records*. Conceptually, *All Selected records* is the population to be compared. The comparison process works on subpopulations. All records that share the same `BY` values are considered to be a subpopulation. Only records that have the same `BY` values are

compared. Other records that have a disjunct set of BY values are part of other subpopulations that are also compared internally.

Within the subpopulation, one or more records are identified by the BASE specification. Ideally, this is a single record, but it can also be a set of several records. If this is a single record, it is called the baseline record. If the BASE specification does not identify a single record, one of the records from the BASE set is selected to be the baseline record. For information about how a record is selected as the baseline, see "Selecting the baseline record."

Within the subpopulation, all records are compared against the baseline record. The comparison is done only for the fields explicitly selected using the COMPAREOPT specification. All other fields are ignored for the compare processing. The result of the comparison operation is one of the COMPARE_RESULT values which provides information about the type of change. For example, a COMPARE_RESULT value can be ADD if the field was added, or CHG if the field value changed. The results can also indicate whether a change resulted in an increase or decrease in the level of security compliance. (See "Defining variables for comparison results (COMPAREOPT)" on page 754.

If the COMPARE_RESULT matches the SHOW specification, the record is kept. If the COMPARE_RESULT does not match the SHOW specification, the record is discarded, which results in a reduced subpopulation.

If the output specification (SORTLIST or DISPLAY) for the record contains a variable defined as COMPARE_CHANGES, the variable is updated to include the changed fields that are selected by the SHOW specification.

The next stage of the compare process is the summary. This stage uses the standard summary process that works on the reduced population (that is, the combination of all reduced subpopulations). The summary processing uses the summary variables as defined in the summary statement.

Selecting the baseline record

If the BASE specification does not result in a single record within the subpopulation, an arbitrary record is selected to be the baseline record. This selection is based on the fields specified on the sortlist and summary statements in this NEWLIST. The record with the lowest field value in the sequence as defined by the sortlist and summary fields is used. If multiple records have the same values for all listed fields, an arbitrary record is chosen. The record selected is not important because the difference is not visible.

No direct relationship exists between the record key that uniquely identifies the record, the list of BY fields, or the list of fields used for summary processing. However, if no list of BY fields has been specified, the program uses a default set of BY fields that resembles the unique record key.

Creating the DEFAULT COMPAREOPT specification

zSecure includes a pre-defined COMPAREOPT specification with the name DEFAULT that can be used to trigger default compare processing when the COMPAREOPT specification is not explicitly defined using the COMPAREOPT statement. This default specification is established using the ALLOC FUNCTION BASE*name* option without specifying a complex name.

The DEFAULT COMPAREOPT specification is equivalent to specifying the following COMPAREOPT statement:

```
COMPAREOPT NAME=DEFAULT TYPE=<anything> BASE=(COMPLEX=complex) SHOW=DIFF
```

Note: Because the DEFAULT specification applies to multiple NEWLIST types, this COMPAREOPT specification cannot be entered as a valid CARLa statement. It is only shown here to illustrate what is specified by the default.

The default COMPAREOPT specification does not specify values for BY and COMPARE. The default specifications are used for these parameters. (See "Selecting the baseline record" on page 48.)

Use of the FUNCTION=BASE specification is not required. It is used to trigger default compare processing. Explicit compare processing using the COMPAREOPT parameter on the NEWLIST statement is possible without any FUNCTION=BASE specification.

For more information, on the syntax and processing considerations, see the FUNCTION=BASE parameter in "Explicit allocation mode" on page 720.

Setting up the CARLa language input for compare processing

Table 15 provides a summary of the statements and formatting options that you can use to setup a compare process. For more detailed information about any of the resources, see the links included in the process description fields.

Table 15. CARLa commands, options and output formats for compare processing

CARLa command, option, or output format	Description
COMPAREOPT statement	This CARLa statement specifies what is to be compared in a comparison process. After the COMPAREOPT specification has been created, the compare process it defines can be run for supported NEWLIST types. See "COMPAREOPT" on page 739.
ALLOCATE FUNCTION=BASE	Use this option to specify a default baseline data set to be used for compare processing. If no explicit COMPAREOPT statements are defined, this baseline data set is used. The FUNCTION=BASE specification is not required for compare processing. However, it can be used to trigger default compare processing when no explicit COMPAREOPT statement has been defined. See the FUNCTION=BASE parameter description in "Explicit allocation mode" on page 720.
NEWLIST COMPAREOPT=compareopt	The COMPAREOPT keyword on the NEWLIST statement specifies the name of the COMPAREOPT statement to be used for the NEWLIST. See "NEWLIST" on page 846.
OPTION COMPAREOPT=compareopt	The COMPAREOPT=compareopt parameter for the Option command designates a default COMPAREOPT statement to be used for all newlists that do not explicitly specify a COMPAREOPT name. You can specify DEFAULT for the compareopt value to use a system-defined default COMPAREOPT specification. See "OPTION" on page 856.
DEFINE COMPARE_RESULT COMPARE_CHANGES	These defined variable fields are used to output the results of a compare operation that includes information about changed fields and a security compliance status indicator that indicates how the change impacted the level of security compliance. The field values included in the output depend on the options specified in the COMPAREOPT statement. See "Defining variables for comparison results (COMPAREOPT)" on page 754.
Output formats	For information about formatting options for the results of a compare operation (COMPARE_RESULT), see "COMPARE processing output formats: Formatting COMPARE_CHANGES results" on page 829.

Chapter 2. RACF Administration Guide

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS

General information

The interactive component of Security zSecure is an ISPF application available under MVS/TSO.

For details on how to start this component, see "Starting the interactive component" on page 9. For information about the ISPF panels in the product, see "Panel structure" on page 10.

Use the **RA RACF** option from the main menu to open the RACF administration menu shown in Figure 36.

```
Menu         Options       Info     Commands     Setup
_____________________________________________________________________________

Figure 36. The RACF administration menu

For more information, see the following topics:

- "Performing RACF Administration tasks from the menu" on page 52
- "Using the RACF administration panels" on page 52
- "Line commands" on page 54
- "Managing the Access List display panel" on page 81
- "REFRESH - Automatic refreshes for RACLIST, GENERIC checking, GLOBAL access checking, and WHEN(PROGRAM)" on page 86

Performing RACF Administration tasks from the menu

Table 16 describes the options available for RACF administration.

Table 16. RACF Administration Menu option descriptions

Option	Description
"RA.U USER - User information" on page 87	Creates general ISPF display panels showing information about all or selected user profiles.
"RA.G GROUP - Group information" on page 117	Creates general ISPF display panels showing information about all or selected group profiles.
"RA.D DATASET - Dataset profiles" on page 132	Create general ISPF display panels showing information about all or selected DATASET profiles. This option is only applicable to auditing RACF databases on a z/OS system.
"RA.R RESOURCE - General Resource profiles" on page 147	Creates general ISPF display panels showing information about all or selected general resource profiles.
"RA.S SETTINGS - SETROPTS and class settings" on page 172	Creates display panels showing information about the SETROPTS settings and the Class Descriptor Table.
"RA.H HELPDESK - One-panel help desk options" on page 177	Opens the one-panel Help desk interface for administrative tasks like resetting passwords, resuming users and using CKGRACF scoping.
"RA.Q QUICK ADMIN - Quick User Administration" on page 179	Opens the three-panel Quick Admin interface for administrative tasks like resetting passwords, resuming users and using CKGRACF scoping.
"RA.1 ACCESS - Access Check" on page 184	Research user and group access level to data sets or resources.
"RA.2 QUEUED - Queued commands" on page 185	Work with queued commands
"RA.3 Reports - Reports with profiles and resources" on page 193	Create printed or online, interactive reports for day-to-day maintenance tasks. zSecure provides sample reports that you can use to design and create custom reports for your site. For information, see "Predefined CARLa scripts" on page 251.
"RA.4 MASS UPDATE - Specify mass copy/recreate/delete actions" on page 233	Perform day-to-day maintenance on groups of profiles.
"RA.5 DIGTCERT - Work with digital certificates" on page 244	Manage digital certificates.
"RA.C CUSTOM - User Defined Display (Custom Display)" on page 249	Use a template to design your own query panel in ISPF.

Using the RACF administration panels

When you perform RACF administrative tasks using zSecure, you use several different types of ISPF panels. The options available on the panels and the methods for using fields and running commands can be different depending on the type of panel you are viewing. Review the following information to learn about the panels, fields, and the selection and viewing options.

Panel types. Depending on the suboption you select from the menu, the resulting ISPF display panel can be a standard display panel or a report display panel. The type of display panel determines the available operations. For example, the line commands available on a report display panel are different from the commands available on a standard display. For more information, see "Line commands" on page 54.

When multiple complexes are selected with the `SETUP` files and `SETUP VIEW` option, the option **Add summary to RA displays for multiple complexes** is selected. As a result of this selection, a summary showing the profile differences is added to the **RA.U**, **RA.G**, **RA.D**, and **RA.R** display panels.

- For text fields, the text is shown when it is identical for the selected profiles. When the profiles are different, the text is shown with a common prefix followed by `>`, the text `<more>`, or `+ *` depending on the column width.
- For flag fields, the percentage of true conditions is shown.
- For date fields, depending on the field, the newest or oldest date is displayed. For example, the oldest date is shown for the profile creation date while the newest date is shown for the password change date.

Another type of panel in the product is a selection panel. Use selection panels for specifying the criteria to select information from a data source for review and analysis in zSecure. Only profiles that match all criteria are selected. That is, the effect of a query is to combine the conditions with AND logic before selecting data.

Field processing and filters. If you leave a field in a panel blank, the field is not tested. Fields on selection panels can contain literals or filters, although not all fields accept filters. The following special characters are supported in filters:

Table 17. Filter characteristics

Filter Code	Description
%	Matches any one non-blank character.
*	Matches up to eight characters in the key of a DATASET profile, or any number of characters in one qualifier in other places.
.**	Matches any numbers of qualifiers at the end of a profile name.
:	Searches for the specified substring anywhere in the field. This function is not supported in profile keys, class names, and data set qualifiers.

Viewing details and printing information. In an ISPF display panel, you can generally select rows from the table to display additional information. You can use the primary command PRT or PRTLIST to create a hardcopy of the tables displayed, written to the standard ISPF LIST data set; you can print the ISPF LIST data set from any ISPF panel by issuing the LIST primary command.

Changing field values. If you use zSecure Admin or IBM Security zSecure Admin and Audit for RACF, you can use modifiable fields. This functionality is not available if you only use zSecure Audit. Modifiable fields are fields that you can update. These fields are also referred to as *overtypeable* fields. Profile display fields that you can type over are shown padded with underline characters. You can specify a different character indicator from the ISPF primary menu (option **0 Settings**). The ability to modify fields is a system-defined setting. Use the MODIFY command to turn this function on and off. Additional display options like confirmation level for commands generated, can be set using the SET command.

Line commands

Commands can be generated by typing over a field or by issuing a line command at the start of a line. The line commands available on an ISPF panel depend on the information shown (NEWLIST type) and the profile type such as user profile or DATASET profile (ENTITY type). In addition, the commands specific to zSecure Admin are only supported if that product is installed and active along with zSecure Audit.

For more information, see the following topics:

- "Determining which line commands are available"
- "Standard line commands"
- "Line commands on profile displays" on page 55
- "Line commands on detail displays" on page 74
- "Line commands on non-profile displays" on page 80
- "Line command status messages" on page 80

Determining which line commands are available

In any profile level display, type / in the input entry field. Then, press **Enter** to view a list of the available line commands and their associated functions.

Standard line commands

Documentation for the line commands available on specific RACF profile display panels for user, group, DATASET, and general resource profiles are listed in the documentation for each profile type. To access this information, see the "Performing RACF Administration tasks from the menu" on page 52. Most other profile level displays, such as specific reports, provide the standard line commands listed in Table 18.

Table 18. Standard line commands

Line command	Meaning
/	Type / in an input entry field and press **Enter** to view a list of the line commands available in the current program context.
B	Browse a data set. This command is only valid for non-VSAM data set objects.
C	Copy the profile. The processing for the copy operation depends on the profile type: • If the copy action is for a data set, connect, or general resource profile, running the **C** line command issues a RACF **COPY** command. • For user and group profiles, running the **C** line command issues a Security zSecure command. These commands are always queued in the CKR2PASS file for later execution. Before the command is run or queued, you are prompted with a panel to edit the profile name.
D	Delete the profile. Depending on the profile type, this issues a RACF command (data set, connect, and general resource profiles) or a Security zSecure command (user and group profiles). Security zSecure commands are always queued in the CKR2PASS file for later execution.
L	Issue a LIST command for a DATASET profile, LISTDSD for example. Use this command for reviewing profile status in the active RACF database.
S	Show detail information for the selected profile.

Line commands on profile displays

The following line commands are available on profile displays.

A - Authorizations of a user or group

Use the **A** line command to find the authorizations defined for a user or group. It can only be issued on user or group profiles on profile displays.

This command starts option **RA.3.4** PERMIT/SCOPE for the user or group it is issued for. See "RA.3.4 Permit/Scope - Report access of a user or group" on page 207.

AC - Access

Use the **AC** line command to find the access defined for a user or group on a specified profile. It can be issued on any profile on profile displays.

It opens option **RA.1** ACCESS for the profile it is issued for. For details, see "RA.1 ACCESS - Access Check" on page 184.

This command is only supported if zSecure Admin is installed and active.

C - Copy

Use the **C** line command to copy a profile through a recursive query. For users and groups, you can also use this command for copying ID-specific DATASET, resource profiles, and catalog aliases if a `CKFREEZE` data set with a master catalog dump is provided. For more information, see the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*

This command is only supported if zSecure Admin is installed and active.

For DATASET or resource profiles you can also issue a RACF command to copy from a profile directly or create a temporary profile. If you have an active RACF database allocated, the latter two options open the newly created profile immediately. For temporary profiles, specify either the date of removal, or a number of days after which the profile is to be removed by the daily `CKGRACF` job. (See the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.) An optional reason for the temporary profile can be specified as well.

Apart from creating new profiles you can also use this function to copy connect definitions and permits to an existing user or group.

The panel it starts for a group is shown in Figure 37 on page 56.

```
 Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - RACF - Group Copy
Command ===>_____________________________________________________________

From group  . . . . C##BDOC
To id . . . . . . . ________

OMVS gid  . . . . . ___________   (numeric id(suffix S for SHARED) or AUTO)

_  Copy permits only (target id may be a group or a user)
_  Generate RACF commands even when the target group exists
_  Copy CUSTOMDATA

Specify options for new group
/  Copy catalog aliases (only if CKFREEZE is present)
/  Issue ADDSD/RDEF for user resources
_  Copy RACFVARS profiles/members too (if option above selected)
```

Figure 37. GROUP COPY panel

The profile used as a model is shown at the top of the panel. In the **To id** field, specify the user or group to copy to. The **Generate RACF commands even when the target group exists** option forces the program to generate commands even when the user exists. A similar option is available on the User Copy panel.

When you copy a group, you can specify an OMVS GID to add an OMVS segment and assign the specified GID. When suffixed with an S (`1001S`, for example), the `SHARED` command keyword is added. You can also specify AUTO, which results in addition of the `AUTOGID` command keyword. The `SHARED` and `AUTOGID` command keywords are available in z/OS 1.4 or with APAR OW52135. On the User Copy panel, the option **Specify unique segment data** can be selected. This option opens a panel for specifying unique segment data. That is, the fields which normally are different for every segment type.

You must specify the **Copy permits only** option to permit copy operations from a group to a user or vice versa. The exact differences between a `COPY USER/GROUP` and a `COPY PERMIT` are detailed in "COPY" on page 740.

Use the options at the bottom of the panel to suppress the following actions:

- Cloning of catalog aliases.
- Cloning group-specific data set and general resource profiles along with catalog aliases.
- Only cloning of `RACFVARS` general resource profiles.

By default, the occurrence of a valid group ID as a member or key of a `RACFVARS` profile is considered meaningful, although RACF itself assigns no specific meaning to these occurrences.

For digital certificates some restrictions apply to the copying of profiles, due to the nature of the `RACDCERT` commands:

- Profiles in the `DIGTCERT` and `DIGTNMAP` classes cannot be copied directly.
- When copying a user profile with connected digital certificates, the latter cannot be copied.

To copy one or more model profiles, use option **RA.4 Mass update** - see "RA.4 MASS UPDATE - Specify mass copy/recreate/delete actions" on page 233.

CC - Copy to a different class

Use the **CC** line command for copying a general resource profile to a different class. It starts an equivalent to option **RA.4.3 Copy resource** for the profile it is

issued for.

```
 Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - RACF - Resource Copy-Class
Command ===>

Copy general profile:
Class name  . . . . ACCTNUM
Profile pattern . . DUMMY

To class  . . . . . NEWCLASS
```

Figure 38. RESOURCE COPY-CLASS panel

To copy the profile, specify the class in the **To class**, then press **Enter**.

This command is only supported if zSecure Admin is installed and active.

CO - Add connect

Use the **CO** line command to add a connection to the group the command is issued for.

The panel it starts for a user is shown in Figure 39.

```
 Menu  Options  Info  Commands  Setup
------------------------------------------------------------------------------
                     zSecure Suite - RACF - Add connect
Command ===> ____________________________________________________________

Create new connect
Userid  . . . . . . . . AUDIT     (user profile key)
Group . . . . . . . . . SYS*____  (group or filter)

Optional connect attributes
Authority . . . . . . . USE_____  (USE ,CREATE ,JOIN or CONNECT)
Default UACC  . . . . . NONE____  (N/R/U/C/A)
Connect owner . . . . . ________
Future revoke date  . . ________  (MM/DD/YY)
Future resume date  . . ________  (MM/DD/YY)
_  Revoke
_  Special          _  Operations       _  Auditor

Enter a group for a single connect.
Leave the field blank or enter a filter (e.g. SYS*) to get a selection list.
```

Figure 39. USER CONNECT panel

This command is only supported if zSecure Admin is installed and active.

When the CO command is issued for a GROUP, you can specify up to 10 IDs for connects.

When a group is entered in the group field, the connect command is generated. When the group field is left blank or a filter is used, a connect list is shown.

```
Add connects for userid AUDIT
 Command ===> _____________________________________________ Scroll===> CSR

Type CO in front of a group to add connect
   group    Complex   InstData
__ SYSAPPL  DINO      APPLICATION DATA
__ SYSAUTH  DINO      AUTHORIZATION GROUPS
__ SYSCTLG  DINO      CATALOG MANAGEMENT
****************************** Bottom of Data ******************************
```

Figure 40. Connecting via group filter

On this list, the **CO** action command generates a connect command with the parameters as specified in Figure 39 on page 57.

D or DD - Delete

Use the **D** line command to delete a profile and all references to it. The profile-related information that you can delete depends on the type of profile you are deleting.

- For users and groups, you can delete ID-specific profiles.
- For groups, you can also delete all related users when you delete the group profile.
- For DATASET profiles, you can also delete the covered data sets if you have specified a CKFREEZE data set as a data source. For more information, see the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

You can also use the **DD** block line command to delete multiple profiles. Block commands must always be used in pairs. To mark the profiles, type a **DD** line command in the selection field for the first and last profile in the set of profiles to delete.

This command is only supported if zSecure Admin is installed and enabled.

When you run the **D** command for a group profile, the panel shown in Figure 41 is displayed.

```
  Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - RACF - Group Delete
Option  ===>

Group . . . . . . . C##BDOC

Specify action to perform
_  1. Delete group
   2. Remove group from resource profiles (remove permit)

Options for delete group                        Options for connected users
Enter "/" to select option(s)                   Delete all USERs ...
/  Dataset and id-specific profiles              _  owned by GROUP
   Only if previous is selected:                 _  connected to GROUP
   _  RACFVARS profiles and members              _  with defaultgrp GROUP
   /  Data sets and their catalog entries        Or move USERs to holding
   /  Incl. catalog entries without data sets           group ________
   /  Incl. uncataloged data sets

Change USERID in Notify fields to   ________  (default is NONOTIFY)
New Owner for non-dataset profiles  ________  (default is SYS1)
```

Figure 41. GROUP DELETE panel

The profile being deleted is shown at the top of the panel.

Select option **2** to only delete permits. To delete the group profile and all associated references, selection option **1**. When deleting a user profile, you can specify the following additional options for the delete action like moving the user to a holding group or only deleting occurrences in NOTIFY fields.

Dataset and id-specific profiles
Delete DATASET profiles and profiles where the ID occurs in a functional position. For more information, see "REMOVE" on page 870.

Options for connected users
Specifying users in a particular relation to the group that must be deleted or moved to a holding group.

Options for other id references
Specify replacement NOTIFY user IDs and owner IDs to replace those IDs that are deleted.

Any RACF and TSO commands created as a result of the query are sent to the CKRCMD file where you can review them. You can submit the commands from the CKRCMD file when you are ready.

For more information, refer to "RA.4 MASS UPDATE - Specify mass copy/recreate/delete actions" on page 233.

E - Event

Use the **E** line command to search for SMF events associated with the current or selected profile. You can issue this command on user, group, DATASET, and general resource profiles on profile displays.

This line command opens the Event panel for user, group, resource, or DATASET profiles depending on the profile type currently being viewed, which is equivalent to selecting the **EV.U**, **G**, **R**, or **D,** option from the Events menu. See "Interactive SMF processing for RACF" on page 550.

This command is only available if zSecure Audit is installed and active.

K - Manage APPCLU and PTKDATA keys

Use the **K** line command for changing, setting, or deleting the APPCLU session key or the PTKTDATA key value. This command is only permitted when the command is issued for an APPCLU SESSION segment or PTKTDATA SSIGNON segment.

When you run the **K** line command, the APPCLU session key panel opens, as shown in the following figure:

```
 Menu  Options  Info  Commands  Setup
--------------------------------------------------------------------------------
                     zSecure Suite - APPCLU session key
Command ===> ____________________________________________________________

Class . . . . . . . . : APPCLU
Profile key . . . . . : NETWORK.LU001.LU002

Select the command you want to execute
_  1. Change or add session key ____________________  (hex x'hhhhhhhhhhhhhhhh'
      or character cccccccc)
   2. Delete session key
```

When option **1** (Change or add session key) is selected, you are required to specify the new session key. You can specify the key as a 1-8 character string or

a 1-16-digit hexadecimal number. Specify hexadecimal values as x'hhhhhhhhhhhhhhhh'. Use option **2** to delete the session key.

When you enter the **K** line command for the SSIGNON segment, the PTKTDATA key panel opens as shown in Figure 42.

```
 Menu         Options       Info    Commands     Setup
------------------------------------------------------------------------------
                        zSecure Suite - PTKTDATA key value
 Command ===> ____________________________________________________________

 Class . . . . . . . . : PTKTDATA
 Profile key . . . . . : MVSDINO.CRMRBYT

 Select the method you want to use to protect the key value
 1  1. Mask the key value using the masking algorithm
    2. Encrypt the key value (requires active cryptographic product)

 Key value . . . . . . . _________________  (16 hexadecimal characters)
```

Figure 42. PTKTDATA key value panel

From this panel, you can define the application key or a secured signon key and indicate the method for protecting the key value within the RACF database on the host. When defining the profile, you can either mask or encrypt the key. The key-value represents a 64-bit (8-byte) key that must be represented as 16 hexadecimal characters. The valid characters are *0-9* and *A-F*.

L - List

Use the **L** List line command for listing the current or selected profile. This command issues the appropriate RACF commands to list the profile. This behavior can be different depending on the profile class. It can be issued on any profile on profile displays.

The results of a listuser, listgrp, listdsd, rlist, or racdcert list command is presented in a browse panel.

To see the data sets covered by a DATASET profile, use either the **LD** (Listdsd DSNS) or the **LR** (List data sets covered via the Report line command).

LD - Listdsd DSNS

Use the **LD** (Listdsd DSNS) line command for listing the current or selected DATASET profile including the data sets covered by the profile. When this command runs, it issues a RACF listsdsd command with the DSNS keyword parameter.

Note: The **LD** line command only lists the data sets where the volume is online.

The results are shown in a browse panel.

LR - List data sets covered via Report

Use the **LR** (List via Report) line command for listing the data sets covered by the current or selected DATASET profile. When you run this command, it issues a recursive Security zSecure query.

Issuing a REPORT PROFILES type query has certain advantages over a RACF **LISTDSD DSNS** command apart from presentation. For more information, see "RA.3.1 Profiles - Profiles with their data sets" on page 196. Tape data sets on scratch tapes are not included in this standard query.

Also, CKGRACF permission is taken into account for the scope that determines what results you can see.

M - Move a user to another group

Use the **M** line command to move a user to a different department.

This command is only supported if zSecure Admin is installed and active.

The panel shown in Figure 43 opens when you run the M command.

```
 Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - RACF - User Move
Option  ===>

Userid  . . . . . . C##BAHI

Move userid from or between groups

Group(s) from which user is to be moved:
________ ________ ________ ________ ________
________ ________ ________ ________ ________

Group(s) to which user is to be moved:
________ ________ ________ ________ ________
________ ________ ________ ________ ________
```

Figure 43. MOVE USER panel

The user you are moving is shown at the top.

You can specify one or more groups to remove the user from, and you can also specify one or more groups to connect the user to.

Connects are removed and created in accordance, and permits to group data set profiles of the old groups are removed as well.

MI - Manage information

Use the **MI** line command for viewing or modifying certain information contained in the profile it is issued for. The modify function is only available if the zSecure Admin product is active.

The panel it starts for a user is shown in Figure 44.

```
 Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - RACF - User Information
 Command ===>

 Userid  . . . . . . USR0001

 Owner . . . . . . . C##B____
 Default group . . . C##B____
 Programmer name . . USER 0001________

 Installation data . TESTUSER FOR 2000-TEST, ESPECIALLY TO TEST THE    RACF DATA
BASE_____________________________________________________________________________
_____________________________________________________________________________

 (as formatted by    RACF DATABASE
  RACF LISTUSER
  command output)
```

Figure 44. MANAGE USER INFORMATION panel

ML - Manage logon information

Use the **ML** line command for the following tasks:

- Revoke or resume a user either now or at a future date using a RACF function. To work with CKGRACF revoke/resume schedules, use the **MS** (CKGRACF Schedule) line command instead of this one.
- Change the password interval for a user ID.
- Set or delete the CKGRACF default password for a user ID.

The user you are working with is shown at the top. The installation data as formatted by the RACF `listuser` command is shown at the bottom.

The user information fields for User, DATASET, Group, and General resource profiles are listed in the following sections. You can modify the information in these fields. When you change the data, an appropriate command is generated.

User profile information fields
Table 19 list the information fields for user profiles.

Table 19. User profiles: User information fields

Field name	Description
Owner	The profile owner field
Default group	The user default group
Programmer name	The name associated with the user ID.
Installation data	The installation data

Group profile user information fields
Table 20 list the information fields for group profiles.

Table 20. Group profiles: User information fields

Field name	Description
Superior group	The `supgroup` field of the group
Owner	The profile owner field
Installation data	The installation data

DATASET profile user information fields
The only user information field for DATASET profiles is the **Installation data** field.

General resource profile user information fields
Table 21 list the information fields for group profiles. You can modify the information in these fields.

Table 21. General resource profiles: User information fields

Field	Description
Application data	The APPLDATA of the resource profile.
Installation data	The installation data.

This command is only supported if zSecure Admin is installed and active.

When you issue the **ML** line command, the panel shown in Figure 45 on page 63 opens.

```
 Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                        zSecure Suite - RACF - User Manage logon-data
Command ===>

Userid  . . . . . . . : USR0001

Revoke date . . . . __________ (dd mmm yyyy, ddmmmyyyy, yyyy-mm-dd, or NOW)
Resume date . . . . __________ (dd mmm yyyy, ddmmmyyyy, yyyy-mm-dd, or NOW)

Password interval 30_   (NO or number)

Default password
_  1. Set password      ==>           ==>
   2. Delete password
```

Figure 45. LOGON DATA panel

The user you are working with is shown at the top.

To revoke or resume the user immediately, type *NOW* in the revoke date or resume date field. To perform the action at a later date, enter the date instead in one of the following date formats:

- *ddmmmyyyy*, 01jan2002 for example.
- *dd mmm yyyy*, 01 jan 2002 for example.
- *yyyy-mm-dd*, 2002-01-01 for example.

To set up a password that does not require the user to change it, specify *NO* for the password interval. To specify a password interval, enter the number of days up to a maximum of 254.

To set a CKGRACF default password, select **1 Default password**. Then, enter the password twice. To delete a CKGRACF default password, select **2 Delete**. Do not select a default password action if you want empty if you want To retain the CKGRACF default password, do not select a default password action.

If you set a CKGRACF default password for a user, it does not change the current password. To change the current password to this value, run the **P** (Password) line command.

MR - CKGRACF multiple authority requirement

Use the **MR** line command to show or change the CKGRACF multiple-authority requirement for a profile. This command can be issued on any profile in a profile display panel.

The CKGRACF multiple authority requirement specifies the number of administrators required to approve a CKGRACF command that targets the profile. This requirement only applies to commands that are subject to multiple authority. See “RA.2 QUEUED - Queued commands” on page 185.

This command is only supported if zSecure Admin is installed and active.

The **MR** line command starts the panel shown in Figure 46 on page 64.

```
 Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - RACF - Authority requirement
Command ===>

Class . . . . . : DATASET
Profile . . . . . : C##QAU3.**

List or set authority requirement for profile:
5  1. List
   2. Single
   3. Dual
   4. Triple
   5. Default
```

Figure 46. MULTIPLE AUTHORITY panel

The class and name of the profile you are now working with are shown at the top.

Use the **List or set authority requirement for profile** to specify the multiple authority setting for profiles.

In each case, a `CKGRACF AUTHORITY` command is generated.

```
  Menu  Utilities  Compilers  Help

```

Figure 47. Multiple authority list result

MS - CKGRACF revoke/resume schedules

Use the **MS** line command to show or modify the revoke and resume schedules for a user.

This command is only supported if zSecure Admin is installed and enabled.

Revoke and resume schedules are the way that Security zSecure supports scheduling several revoked or resumed periods for a user. Refer to "Revoke/resume schedules" on page 1543 for an explanation.

This command is only supported if zSecure Admin is installed and enabled.

The **MS** line command starts the panel shown in Figure 48 on page 65.

```
   Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                          zSecure Suite - Manage User Schedules
 Option ===>

1  List           List schedules for this userid
2  Enable         Specify date(s) when user should be able to logon
3  Disable        Specify date(s) when user should not be able to log on
4  Wipe           Remove scheduled events at specified date(s)

 Userid  . . . . . . C##MBTJ2
 Schedule  . . . . . HOLIDAY_

 Start date  . . . . 13FEB1999_        End date  . . . . . 1999-02-22
                                       Number of days  . . ___

 Enter Reason below
'Well, he planned a holiday for when the tape would be ready... /A1'_____________
```

Figure 48. MANAGE SCHEDULE panel

The user ID you are working with is listed after the **Option** selection field. Table 22 describes the fields of interest.

Table 22. MANAGE SCHEDULE panel - field descriptions

Field	Description
Option	Specifies the action for the schedule. The following actions are available: • **1 List** shows the separate scheduled events for the user along with the overall schedule. • **2 Enable** or **3 Disable**, opens a panel for defining a time period during which the user can or cannot logon. Option • **4 Wipe** removes scheduled events from a period.
Schedule	Specifies the start date. Valid date formats are *ddmmmyyyy* and *1999-02-22*. You can also specify *TODAY*. This field is required for all actions except **1 List**.
Start date	The name of the schedule to change. This field is required for all actions except **1 List**.
End date	Specifies that the period to which the action applies extends up to and including this date. This field is optional and mutually exclusive with **Number of days**.
Number of days	The number of days the action is to last. This field is optional and mutually exclusive with **End date**.
Enter reason below	Optional specification of a reason for the action.

Each action results in a `CKGRACF` command. The result is typically shown in a browse panel.

```
COMMAND OUTPUT BROWSE ----------------------------- LINE 00000 Command failed
COMMAND ===>                                          SCROLL ===> CSR

CKGRACF USER C##BJT2 SCHEDULE HOLIDAY DISABLE (13FEB1999:1999-02-22) REQUEST   R
ould be ready... /A1")
CKG633I 08 Access to schedule 'HOLIDAY' denied for command in PARM string
CKG107I 08 Command ended with result code 8
CKG111I 08 Highest result code was 8
CKR962F Command failed, return code 8 (decimal)
******************************** Bottom of Data ******************************
```

Figure 49. Schedule disable result

In this case, the administrator issuing the command was not authorized to update the HOLIDAY schedule.

Figure 50 shows sample results from a LIST command.

```
CKGRACF LIST USER C##CX01 SCHEDULE
CKG132I 00 No CKGRACF queued command entries found
CKG116I 00 Scheduled revoke for HARD on 12Oct1999 by C##SYST 12Oct98 14:38
CKG116I 00 Scheduled resume for HOLIDAY on 01Mar1999 by C##DPT1  4Nov98 13:03
CKG116I 00 Scheduled resume for HOLIDAY on 10Mar1999 by C##DPT1  4Nov98 13:08
CKG116I 00 Scheduled resume for HARD on 12Aug2000 by C##SYST 12Oct98 14:38
Deleted  by C##SYST at 12 Oct 1998 14:39
CKG117I 00 --- Overall revoke/resume status ---
Resumed from  1 Mar 1999
Revoked from 12 Oct 1999
```

Figure 50. Schedule list result

After combining the separate schedules used, the overall revoke and resume status schedule, is shown in the lines preceding the `CKG117I` message. See Figure 50. The separate scheduled events are listed before the schedule it. In this example, no were specified. Message `CKG132I` indicates that no requests for scheduled events are queued for approval. See "RA.2 QUEUED - Queued commands" on page 185.

Because the **MS** line command is a command on the profile level, no scheduled event characteristics are passed. To work with a particular scheduled event, issue a line command for that event from the detail display.

The following line commands are available on a scheduled event:

D (Delete) generates an appropriate wipe command

C (Copy) reissues the command. Depending on your `SETUP CONFIRM` settings, you might have permission to change the command on the confirmation panel. If you do, you can use the panel as a template.

S (Select) shows the scheduled event in a more readable way, being split into items as must be specified on a request panel.

R (Repeat) opens a panel like the one shown in "RA.2 QUEUED - Queued commands" on page 185 with the characteristics of the event included so you can easily repeat it but without the `LIST` option.

I (Insert) opens the same panel without any data so you can add an event.

MT - Manage TSO information

Use the **MT** line command for the following tasks:

- Create a DATASET profile.
- Define a catalog alias in the master catalog.

- Create an ISPF profile data set for the current or selected user ID.

The **MT** command requires sufficient authorization for creating the specified profiles or catalog alias.

```
 Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                         zSecure Suite - RACF - User Manage TSO
Command ===>

Userid for setup . : USR0001

Enter "/" to select option(s):
_  Create dataset profile for user
_  Define ALIAS in the Master Catalog
_  Create ISPF Profile Dataset
```

Figure 51. MANAGE TSO panel

Userid for setup
The user you are working with. This field is non-modifiable.

Create dataset profile for user
If this field is selected (with a /), an `ADDSD userid.** owner(userid)` command is generated, followed by a `SETROPTS REFRESH GENERIC(DATASET)`. Member `C2RSMUMH` in the `CKRPARM` configuration data set can be used to customize the generated commands.

Define ALIAS in the Master Catalog
If this field is selected, an `IDCAMS DEFINE ALIAS` command is generated. Member `C2RSMUMA`, located in the `CKRPARM` configuration data set must be customized to incorporate the User catalog name.

Create ISPF Profile Dataset
If this field is selected, a TSO ALLOC command is generated to create an ISPF profile data set. The data set name `userid.ISPPROF` can be changed by customizing member `C2RSMUMP` (located in the `CKRPARM` configuration data set).

MU - Manage installation-defined USRDATA

Use the **MU** line command for working with `USERDATA.` . It can be issued on any profile on profile displays.

For more information, see “RA.3.9 USERDATA - User data management” on page 219.

P - Change password and resume user

Use the **P** (Password) line command for managing password and password phrases and resuming user IDs. When you issue this command, the shown in Figure 52 on page 68 opens. The available actions are described in Table 23 on page 68. This command is only supported if zSecure Admin is installed and active.

```

Figure 52. PASSWORD panel

Table 23 describes the fields of interest on the RACF User password panel.

Table 23. RACF User password panel - field descriptions

Field	Description
Userid	Displays the currently selected user ID and the following related information: • User name. • Installation data. • Last date and time the user ID was used. • Date of the last password and password phrase change. • A flag indicating whether the user ID has been revoked. • If the user ID has been revoked and resumed, the revoke and resume dates are listed. • A flag indicating whether the user ID is protected. • Current® setting for the *Revoke inactive attribute* that indicates whether the user is effectively revoked due to the `SETROPTS INACTIVE()` setting.

Table 23. RACF User password panel - field descriptions (continued)

Field	Description
Select action	Specifies the action to perform when managing passwords and password phrases. You can select from the following actions. • **1 New password** Specify a new password. You must enter the new password twice. • **2 DEFAULT password** Set the password to the default password. • **3 PREVIOUS password** Set the user password back to its previous value. • **4 RANDOM password** Set the user password to some unknown value to ensure that the user ID cannot be used to logon. • **5 Resume only** Resume the user without changing the password. • **6 Current password** Resume the user ID and set the password to expired. • **7 Make Protected** Protect the user ID so that it does not have any password and cannot be used to logon. • **8 New password phrase** Add or remove a password phrase. Actions **2**, **3**, and **4** generate `CKGRACF` commands. Actions following actions **1**, **5**, **7**, and **8** generate either RACF or `CKGRACF` commands, depending on the `SETUP CONFIRM` settings.

Notes:

1. Setting a non-expired password might require more authorization than setting an expired one.
2. You can set the `CKGRACF` default password through the **ML** Manage Logon information line command.

`PE - Add or delete permit`

Use the **PE** line command for adding or deleting a permit for any profile type. This command is available for all profiles. This command is only supported if zSecure Admin is installed and active.

When you issue the **PE** command for a user or group, you can specify the DATASET or general resource profile for which you want to add or remove the permit. When issued for a DATASET or general resource profile, you can add permits for up to 10 users or groups. You can use a pseudo-access level `DELETE` to delete a permit.

Figure 53 on page 70 shows the panel that opens when you issue a **PE** command.

```
 Menu  Options  Info  Commands  Setup

   Class    Profile                                    Type    InstData
__ DATASET  SYS1.*.**                                  GENERIC
__ DATASET  SYS1.*.MAN*.**                             GENERIC
__ DATASET  SYS1.ACDS                                  GENERIC
__ DATASET  SYS1.BRODCAST                              GENERIC
****************************** Bottom of Data ********************************
```

Figure 54. Adding permits using a mask

If you select a DATASET or general resource profile, you can specify up to 10 user IDs.

On this list, the PE action command generates a Permit command with the parameters as specified on the previous panel.

R or RR- Recreate a profile

Use the **R** line command on any profile in a profile display to generate the commands to recreate the profile. For user and groups, you can also recreate the associated access list entries and DATASET and resource profiles. It can also be used to recreate segments by issuing the command on a segment display.

This command is only supported if zSecure Admin is installed and active.

Use this command for restoring a profile that was inadvertently deleted from the database:

1. Restore a version of the database in which the profile still existed to a data set. Then, use it as a COPY.TEMP input data source. See "SE SETUP - Options and input data sets used" on page 1641.
2. Locate the profile of interest in the view of the restored database.
3. Run the **R** line command on the profile.

Note: Using an UNLOAD data set as an input source has the disadvantage that passwords and other sensitive fields are recreated as .********.

You can also use the **R** line command to create a copy of a profile. After running the command, edit the generated commands to create a copy of the profile instead of recreating the same profile.

To recreate multiple profiles at one time, use the block line command **RR**. Block commands must always be used in pairs. To mark the profiles, type an **RR** line command in the selection field for the first and last profile in the set of profiles to recreate.

The **R** line command has the following limitations:

- General Resource profiles in the following classes cannot be recreated using this mechanism: DCEUUIDS, DIGTCERT, DIGTNMAP, DIGTRING, IDIDMAP, UNIXMAP, NDSLINK, NOTELINK, ROLE.
- Certificate, ring, and map connections on a user ID cannot be recreated.
- TAPEDSN profiles cannot be recreated.
- Multivolume discrete data set profiles might be handled incorrectly.
- Discrete profile ADDSD only works if the data set is cataloged, and you might have to add NOSET and VOLUME to the commands.
- Last change time stamps reflect the time the profile was recreated.
- Connect owners are not preserved because RACF commands do not permit arbitrary owners to be specified. Connect owners are not used for RACF authorization decisions.

When you issue the **R** line command for a user, the panel shown in Figure 55 opens.

```
 Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                       zSecure Suite - RACF - User Recreate
Command ===> ____________________________________________________

Recreate userid . . USR0001

Specify options for recreate
/  Copy Dataset and General Resource profiles for this user
/  Copy Access List entries with this user
/  Use CKGRACF to update the user profile
```

Figure 55. USER RECREATE panel

The profile you are recreating is shown at the top.

You can specify whether the commands generated to update the profile can include CKGRACF commands. For a user or group, you can opt to restore access list entries and associated DATASET and general resource profiles as well.

Figure 56 on page 72 shows a sample of the results of a RECREATE command operation.

Figure 56. Recreate results

For more information, see "RA.4 MASS UPDATE - Specify mass copy/recreate/delete actions" on page 233.

S - Select

The **S** line command is available on all profiles, provided additional information was requested in your query. Issuing this line command opens an ISPF panel that shows more detailed information about the profile.

SE - Show application segments

Use the **SE** (Segments) line command for generating a recursive query to view the application segments for the current or selected profile. It can be issued on any profile on profile displays.

The advantage of using **SE** to retrieve application segments on a per profile basis instead of specifying that they are always to be included immediately (by tagging **Show segments** and **All** on a profile selection panel) is to limit the required amount of storage. With SE command processing, the program does not have to store all the application segments for the other profiles.

Figure 57 shows the panel that opens when you run the **SE** line command.

```
zSecure Admin Display Selection                  1 s elapsed, 0.3 s CPU

```

Figure 60. All relevant user information

TR - Trust bestowed on userid

Use the **TR** action command for running a TRUSTED report for the current or selected user. This command is only supported if zSecure Audit is installed and configured.

For additional information, see "TRUSTUSR - Trusted users report" on page 292.

X or XX- Exclude a profile from FORALL processing

Use the **X** line command to exclude a profile from FORALL processing. To exclude multiple profiles, type **X** in the selection field for each profile to exclude. You can also use the **XX** block command to exclude a block of profiles. This line command must be used in pairs. To mark the profiles, type the **XX** line command in the selection field for the first and last profile in the set of profiles to be excluded.

You cannot combine the Exclude (**X** or **XX**) line command with the Select line command (**Z** or **ZZ**).For more information, see the "FORALL command" on page 13.

Z or ZZ - Select a profile from FORALL processing

Use the **Z** line command to select a profile for FORALL processing. To select multiple profiles, type **Z** in the selection field for each profile to select. You can also use the block command to mark the beginning and end of the set of profiles to be selected. You cannot combine the Include line command (**Z**, **ZZ**) with the Exclude (**X**, **XX**) line commands. For more information, see the "FORALL command" on page 13.

34 - Data set list utility

This action command invokes program ISRUDL, which can also be called using IBM ISPF option 3.4. The action command is available on user, group, and DATASET profile overviews. When this command is run, a data set list panel is displayed with the profile in the dsname level.

Line commands on detail displays

The line commands available on detail displays depend on the type of field that is shown. Most fields support the following standard line commands listed in Table 25 on page 75.

Table 25. Standard line commands available on detail displays

Line command	Meaning
C	Copy the field or entry. For example, issuing the **C** command for an access list entry creates a `PERMIT` command to add a new access list entry with the same permissions. Before the command is run or queued, you are prompted with a panel to edit the key or profile name.
D	Delete the field or entry. For example, issuing the **D** command before a volume serial generates an `ALTDSD DELVOL` command.
L	Use the **`LIST`** line command to list the information for the currently selected entry. For example, issuing an L command before a NOTIFY field generates a `LISTUSER` command.

Note: If your installation is configured to queue generated commands before running them, you view and manage any commands generated by a line command through the **RA.2 Queued commands** option. See "RA.2 QUEUED - Queued commands" on page 185.

Some detail views support additional line commands. For more information, see the following topics.

- "Access List detail view"
- "Connect detail view" on page 77
- "Data set detail view" on page 78
- "Digital Certificate detail view" on page 78
- "USR fields" on page 78
- "RACLINK fields" on page 79

Access List detail view: On access list display panels, the following commands are supported: **L** List, **C** Copy, and **D** Delete, **L** issues a RACF `listuser` or `listgrp` command (as appropriate) and shows the results in a browse panel. You can use the **C** and **D** commands for adding and deleting permits. Figure 61 on page 76 shows a sample of the results.

Optional conditions for the permit
When class . . . . . ________           (was empty)
When resource/profile
_______________________________________________________________________________
_____________________________________________________________(was empty)
```

Figure 62. COPY PERMIT panel

Pressing ENTER generates a command to create a copy of the permit, and presents it in a confirmation panel. The options shown on this panel depend on your SETUP CONFIRM settings. An example is shown in Figure 63 on page 77.

```
                        zSecure Suite - Confirm command
Command ===> ____________________________________________________________

Confirm or edit the following command
permit_CNRACF_class(PROGRAM)_id(C##A)_access(READ)_____________________
_______________________________________________________________________
_______________________________________________________________________

Command execution . 4  1. QUEUE RACF command
                       2. QUEUE CKGRACF command (allows use of Reason)
                       3. ASK administrator to execute CKGRACF command
                       4. REQUEST CKGRACF command for later execution
                       5. WITHDRAW CKGRACF command

Specify date for command to be executed
Start date . . . . .  __________  (ddmmmyyyy, yyyy-mm-dd or TODAY)
Until/for  . . . . .  __________  (ddmmmyyyy, yyyy-mm-dd or number of days)
Reason . . . . . .    ____________________________________________________

Press ENTER to continue or END to cancel the command
```

Figure 63. CONFIRM PERMIT panel

At the top, the command to be generated is shown. The **D** command results in a similar panel.

Connect detail view: On connect displays, **L** List, **C** Copy, and **D** Delete are supported. **L** issues a RACF `listusr` or `listgrp` command as appropriate and shows the results in a browse panel. You can also use the **C** and **D** commands for adding and removing connects. Figure 64 shows an example of the Group detail panel.

Figure 65. COPY CONNECT panel

Data set detail view: When you are in a detail display showing a data set (fields **DSN**, **DATASET**, or **DSNAME)**, you can specify the **B** line command to browse the data set.

Digital Certificate detail view: Certificates are shown for both the USER BASE segment and the DIGTRING CERTDATA segment and are processed slightly differently in each location.

For the USER BASE segment, the certificates created for this user are shown with both **label** and **name**. The following actions commands are supported for both of these fields:

L list generates a RACDCERT LIST command, which is directly run by RACF.

D delete generates a RACDCERT DELETE command, which is presented in a panel like the one for the ACL D (Delete) command.

C copy generates a RACDCERT CONNECT command.

On the DIGTRING CERTDATA segment, the certificates connected to this ring are shown. The following action commands are supported for this segment.

L list and **D** Delete are the same as they are for the

D delete generates a RACDCERT REMOVE command, which is presented in a panel like the one for the ACL DELETE command.

C copy generates a RACDCERT CONNECT command.

These generated commands are shown on a panel where they can be edited if necessary.

USR fields: The USR fields are used for two, mostly separate functions within Security zSecure: *normal* user-defined fields and CKGRACF fields. Different line commands are available for each USR field type. You can view and manage normal user-defined fields through option **RA.3.9 USERDATA**. See "RA.3.9 USERDATA - User data management" on page 219. Table 26 on page 79 describes the line commands available on the detail display for normal, user-defined fields.

Table 26. Normal, user-defined USR fields: available line commands

Line command	Description
C	Copy the USERDATA entry, prompting you for new parameters. The copied entry has the Entry Name, Flag, and Value set as in the repeated entry.
D	Generates a CKGRACF DELETE command.
I	Add a USERDATA field to a specified profile.
R	Generates a CKGRACF REQUEST command with a copy of the current command. You can edit the command before running it.
S	SET. This command takes you to a panel where the current USERDATA field is described completely. You can edit this panel to reflect the changes that you want to make to this field.

You can view and manage the CKGRACF fields through option **RA.2. Queued commands**. See "RA.2 QUEUED - Queued commands" on page 185. Table 27 describes the line commands available on the detail display for CKGRACF USR fields.

Table 27. CKGRACF USR fields: available line commands

Line command	Description
A	Approve the queued command.
C	Copy the USERDATA entry, prompting you for new parameters. The copied entry has the Entry Name, Flag, and Value set as in the repeated entry.
D	Deny the queued command.
H	Generates a CKGRACF HOLD command for the command in the approval queue. Running this command refreshes the last action time stamp of the command, which defers expiration.
I	Specify another command to add to the queue of approved commands.
R	Edit the current command and queue for approval.
S	View the details of the selected command.

RACLINK fields: On User profile detail display panels, you can manage RACLINK associations for a user from the *Linked.node.user* fields available from the User Profile detail view. If the current user has a RACLINK association defined, the information is listed in the *Linked.node.user* field as shown in Figure 66 on page 80. If no RACLINK association is defined, the RACLINK entry fields are empty. However, you can add an association by typing the **I** (Insert) line command in the input field for the *Linked.node.user* entry field.

```

```

Figure 66. RACLINK associations for a user

In Figure 66, IBMUSER has a RACLINK association with the user profile CRMAJEN. Authorized users can modify the values for the *Linked node.user*, *Type*, and Pwd fields by typing over the existing values in these fields. Table 28 lists the line commands available to manage RACLINK associations for the user profile.

Table 28. RACKLINK fields: available line commands

Line command	Description
A	Approve a pending association. This command is only supported for association records having *Pend* status. If the command is issued on an association that is not pending, an error message is displayed.
C	Copy the current RACLINK association. When you run this command, the Copy RACLINK panel opens to complete the copy operation. Press F1 on this panel for help.
D	Generates a RACLINK id (userid) undefine (linked.node.user) command to delete the current RACLINK association. Depending on your Setup Confirmation options (SE.4), when you run this command, it either deletes the association immediately or opens a confirmation panel to set command processing options for deleting the association.
I	Copy or insert a RACLINK association for the current user. When you run this command, the Copy/Insert RACLINK panel opens to specify the information for the association. Press F1 on this panel for help.

Line commands on non-profile displays

Additional line commands are available on certain non-profile displays. These commands are described in the documentation for these panels, "Line commands on the class settings display" on page 176 for example.

Line command status messages

After you specify a line command on an overview or detail display panel and press **Enter**, the corresponding command is generated. A status message is also shown in the upper right corner of the panel to indicate the status of the action. Table 29 provides examples of line command status messages.

Table 29. Line command status messages

Message	Meaning
Successfully modified **Copy successful** **Delete successful**	Indicates that a RACF command was generated and run. The command action must be set to EXECUTE.

Table 29. Line command status messages (continued)

Message	Meaning
Queued in CKRCMD	Indicates that a RACF command was generated and either written to the CKRCMD file for later execution or for submission to another MVS system. The command action must be QUEUE.
Queued in CKR2PASS	Shows that a Security zSecure command was generated and written into the CKR2PASS file. You must run Security zSecure again with these commands as input to generate RACF commands. This message is issued when a user or group profile is copied or deleted. The command action can be either QUEUE or EXECUTE.
Refresh registered	Indicates that a RACF SETROPTS REFRESH command was generated. The command has not been run yet. When you leave the results panel, another panel opens for confirming all generated SETROPTS REFRESH commands. Only the confirmed commands are run. The command action must be set to EXECUTE.

Managing the Access List display panel

When working with profiles in zSecure, you can view and manage the access list for profiles from the profile display panels. You can use the access list information to research access levels and determine how profile changes affect the access list.

You can specify the default format for the access list from on the Setup - View panel available on the SETUP menu. You can also control the format using the ACL primary command from the command line.

Table 30 lists the format options available on the Setup-View panel.

Table 30. Access list format field values

Value	Description
No	Do not show the access list.
Sort	Sort the entries in the access list view by **Id**, **User**, or Access, as specified under the Access list sort column.
Explode	Replaces groups on the access list by the users granted access through the group profile definition and connect attributes. Also adds administrative access. This format is useful for determining the effects of removing a group ID.
Resolve	This format is like the **Explode** option, but shows the resolved access per user: superfluous entries are removed.
Effective	Extends the **Resolve** result by adding users with OPERATIONS or group-OPERATIONS attributes.

If the Access list format field on the Setup - View panel is set to a value other than NO, you can use the ACL primary command to control the data shown on an Access list display panel. Table 31 on page 82 lists the ACL command parameters you can specify.

Table 31. Access list display: ACL primary command parameters

Parameter	Description
EXPLODE	All lines containing a group are replaced by lines for all users connected to the group. Operations access is also shown if the relevant profiles were read, which can be requested through the **Enable full ACL** option. Also shows access permitted by the owner field, group-special, group-operations, connect CREATE authority, class authorization, system operations, or a qualifier.
RESOLVE	Includes 1 line per user or user plus `WHEN(class(profile)` condition, showing actual access. Does not show access permitted by operations, group-operations, or administrative access.
EFFECTIVE	Creates a view like the RESOLVE view but also shows access due to system-wide or group operations. This command requires a full database read using the **Enable full ACL** option. The command fails if a query is run with an indexed read.
NORMAL or **ASIS**	Only show access list entries without exploding or resolving the data.
TRUST	Creates a view like the `EXPLODE` view but provides separate entries for administrative and normal data access.
SCOPE and **NOSCOPE**	Determines whether administrative access is shown in the access list data. This setting is automatically switched to `NOSCOPE` for the following views: `NORMAL`, `RESOLVE`, and `EFFECTIVE`. The setting is automatically switched to `SCOPE` for the `EXPLODE` and `TRUST` views. To change the default setting, you can specify the option behind the ACL primary command, **ACL EXPLODE NOSCOPE** for example.
UNIVERSAL and **NOUNIVERSAL**	Determines whether default connections to universal groups and system-wide operations are used to calculate access.
SORT	Changes the sequence of the data display. See Table 32.

To change the sequence of a display, you can specify the SORT option on the Setup - View panel, or use the SORT parameter with the ACL primary command.Table 32 lists the SORT parameter options.

Table 32. Access list display: ACL command SORT parameter options

Parameter	Description
ID	Sort by ID actually in access list. This option is available for user or group profiles.
USER	Sort by user ID. The user ID can be present in the exploded access list data for a group.
ACCESS	Sort by access level, from high access to low access.

In Figure 67 on page 83 a normal sorted ACL is shown, sorted by User.

```

Figure 69. ACL Display - EXPLODE

The EXPLODE format shows OPERATIONS just like the EFFECTIVE format. The access reported is ALTER-O, which is considered to be higher than ALTER (for the previous SORT order is still active). The user IDs reported with the OPERATIONS attribute are all system-wide OPERATIONS users. For groups with the OPERATIONS attribute, the group is reported under **ACL id** instead of - *oper* -.

A fair number of the users selected might have access through both groups, so after switching to **ACL EFFECTIVE**, some superfluous entries (where the determination of effective access is concerned) are deleted. As a result, the line count goes down.

```

```

Figure 70. ACL Display - EFFECTIVE

In Figure 70, the operations access lines have disappeared because the user ID *C##BMR1* has explicit access through group *C##B*. As a result, the OPERATIONS attribute is effectively ignored.

When ACL RESOLVE is requested now, the first three entries disappear.

Table 33 lists the fields available to show the access list information:

Table 33. Access List: display fields

Field name	Description
User	ID on access list.
Access	Access level.
ACL id	ID mentioned on access list.
When	Condition for this access to be granted.
RI	The user status (inactive, revoked, or pending). This field indicates whether the user would be revoked due to inactivity upon attempting to log on or to start a job. The value takes into account the global SETROPTS INACTIVE setting and the last use date of the user.
Name	The name of the user if the **ACL id** is a user.
DfltGrp	The default connect group of a user. This field is found in USER profiles only.
RvC	This repeat field indicates whether the user has the REVOKE attribute in the connect group entry.
Instdata	The installation data for the user or group on the ACL.

REFRESH - Automatic refreshes for RACLIST, GENERIC checking, GLOBAL access checking, and WHEN(PROGRAM)

The SETROPTS REFRESH panel might be opened after a run if interactive changes were applied to any of the following:

- Profiles in classes that are RACLISTed.
- Generic profiles in classes that have GENERIC checking active.
- Global profiles describing classes for which global access checking is active.
- Program profiles if WHEN(PROGRAM) checking is active.

The SETROPTS refresh panel does not open in the following situations:

- The panel has been deactivated using the options available on the Setup Confirm panel. See "SE.4 Setup - Confirm" on page 1655.
- No SETROPTS commands were generated when changes were applied,
- The SETROPTS REFRESH commands were appended at the end of the CKRCMD file.

Figure 71 shows the SETROPS REFRESH pop-up that opens for confirming the commands.

Figure 71. REFRESH Confirmation panel

The Confirm SETROPTS REFRESH panel presents a list of intended refresh commands. The list includes the refresh type along with the class to be refreshed when the commands run. If applicable, the class list includes other classes that share the same POSIT value and are also sensitive to this type of refresh and therefore affected when the commands run. If you do not want the Refresh command to be run for a specific entry, remove the selection by typing over the / value with a space. Use the scroll down function to review all the Refresh entries in the list. When you are done reviewing the Refresh commands, press **END** to run the Refresh commands for the selected classes.

The following refresh types can be performed:

GENERIC
Refresh the generic profiles

GLOBAL
Refresh the global access checking table

RACLIST
Refresh all profiles (for a RACLISTed class)

WHEN
Refresh WHEN class checking

After the REFRESH commands run, a browse panel opens to show the commands that were run and the result of the action.

RA.U USER - User information

The User Information panel provides access to simple selection functions for user profiles. Using these functions you can perform tasks such as the following:

- Add a new user profile from scratch. See "Add new user or segment" on page 105.
- Specify selection criteria for user profiles. Only profiles that match all criteria are selected. This selection effectively combines all the selection criteria with AND logic. Fields that are left blank are not tested.

```
 Menu   Options   Info   Commands   Setup

_  Print format      _  Customize title  _  Send as email
   _  Background run _  Full page form   _  Sort differently  _  Narrow print
```

Figure 72. Simple user selection screen

For example, you can find all user IDs that have *C##QA0*in the first six positions by typing *C##QA0** in the **Userid** field. The other fields work similarly.

The following simple selection criteria are supported:

Table 34. Simple Selection Criteria

Selection criteria	Description
Userid	This ID, or a matching ID if a filter is used.
Name	Search for the specified string in any position within the name field. You cannot use a filter in this field. A *substring scan* is performed.
Installation data	Find occurrence anywhere in the installation data. You cannot use a filter in this field. When this command runs, a *substring scan* is performed.
Owned by	Search for the specified OWNER. The owner can be a user or group.
Default group	With the following default group.
Connect group	Connected to the specified group.

Additional selection criteria can be requested through the following options which can be selected by entering **/** or **S** in the entry field.

Table 35. Additional Selection Criteria

Selection criteria	Description
Other fields	Use this field for selecting on date fields, complex name, schedule name, or password interval. The selection panel is shown in "Additional selection - Other fields" on page 98. If the field is not selected, the **Other fields** selection criteria are ignored. However, the settings are saved for later use as long as you are using the **RA.U** option.
Attributes	For selecting on the following fields: • Security attributes like special, operations, auditor, revoked, inactive, protected, restricted, and `UAUDIT`. • Presence of logon restrictions, certificates, `raclinks`, and `userdata`, • `CKGRACF` dual or triple authority and queued commands. • User security attributes like special, operations, auditor, revoked, inactive, protected, restricted, `UAUDIT`, and queued commands. The selection panel is shown in "Additional selection - Attributes" on page 101. If the field is not selected, the **Attributes** selection criteria are ignored. However, the settings are saved for later use as long as you are using the **RA.U** option.
Segment presence	If this field is selected, criteria can be specified for the presence of application segments. A segment selection panel and a segment field selection panel are shown. Unless the output option **Show segments** has also been selected, these panels only show the base segment of groups that have the specific non-base segment. If the field is not selected, the selection criteria are not used but are saved for later use as long as you remain in **RA.U**.
Segment absence	If this field is selected, absence of a segment can be specified as an additional selection criterion. If the field is not selected, the selection criteria are not used but are saved for later use as long as you remain in **RA.U**.

Table 36 lists the output and run options you can specify.

Table 36. Output and Run options

Show segments	Show a selectable set of application segments for specifying select and exclude criteria based on segment field values. If this option is not selected, the segment subset is not used but is saved in your ISPF profile for later use. This flag setting is saved in your ISPF profile.
All	Select this option with the *Show segments* to show all segments for the selected users.
Specify scope	If this field is selected, you can limit the results to the scope of a user ID or group.
Print format	If this field is selected, the results are provided is in print format instead of an ISPF display. This flag setting is saved in your ISPF profile and is shared between all **RA** options showing it. The other print-related options only apply if this one has been selected. See also "Print format" on page 113.
Customize title	If this field is selected together with *Print format*, you can change the subtitle for the selection and add an extra title that is saved in your ISPF profile. For example, you might specify a title that shows your company name, department, and phone number. This flag setting is saved in your ISPF profile and is shared between all RA options showing it.

Table 36. Output and Run options (continued)

Send as email	If this field is selected along with **Print format**, then a panel opens for specifying the email address destination for the report. The email function does not work until you have configured the SMTP options with `SETUP OUTPUT`. This flag setting is saved in your ISPF profile and is shared between all `RA` options showing it.
Background run	If this field is selected together with **Print format**, then a batch job is submitted to perform the query. This flag setting is saved in your ISPF profile and is shared by all `RA` options showing it.
Full page form	If this field is selected together with *Print format*, then the report format uses at least one full page per user for the user detail information. This flag setting is saved in your ISPF profile. If you have requested segments, they are shown on the same page with the other user ID information. If the *Full page form* field is not selected, each segment type is shown in its own tabular report.
Sort differently	If this field is selected together with *Print format*, then an alternate sort order can be selected. If you want to change the sort order in an ISPF display (Print format not selected), you can use the SORT primary command in the actual display. This flag setting is saved in your ISPF profile.
Narrow print	If this field is selected together with *Print format*, then the width of the page is limited to 79 characters, independently of the actual print file record length. If the field is not selected, then the page layout you specify must support a width of 132. However, the length can extend beyond that if the print file has a larger record length. This flag setting is saved in your ISPF profile and is shared between all panels displaying this option.

User profile tabular display

A user information panel is shown in Figure 73.

Figure 73. User profile display

Table 37 describes the columns on this panel.

Table 37. User profile tabular display - Column descriptions

Column name	Description
User	RACF user profile name (user ID).
Complex	Name for the RACF security database containing this profile.
Name	Programmer name field of RACF profile. Users can change their own programmer name field.
DfltGrp	Default group for the user. Users can change their own default group. The user can only change the default group to a group that is already connected.
Owner	The owning user or group for the user profile.

Table 37. User profile tabular display - Column descriptions (continued)

Column name	Description
RIRP	Indicates the user status: **R** revoked. **I** due to be revoked through inactivity, **R** restricted, which means that access through the UACC, global, and ID(*) are not honored. **P** protected, which means that user ID cannot be used to logon.
SOA	Indicates the user attributes, Special, Operations, or Auditor.
gC	The **g** column indicates that the user is connected to at least one group with the Special, Operations, or Auditor attribute. The **C** column indicates that the user has at least one class authorization.
LCX	**L** indicates at least one RACLINK. **C** indicates a user certificate. **X** indicates an expired password.
Grp	Number of groups that the user is connected to.

You can scroll the panel to the right to view additional information as shown in Figure 74.

Figure 77. User profile detail display panel

Depending on SETUP options and data availability, the following fields of interest can be shown.

Identification fields

Table 41. User profile detail display - Identification section field values

Field	Description
Identification of	This header line contains the user ID and (far to the right) the complex name.
User name	The name (*programmer name*) of the user. Users can change their own *programmer name* field.
Installation data	Installation data field of the profile.
Owner	The owning group or user ID and is (on the detail display) optionally followed by the owning user name and installation data or the group installation data.
User's default group	The default connect group and is (on the detail display) optionally followed by the group installation data. Users can change their own default group. The user can only change the default group to a group that is already connected to.

Connect group fields

Depending on SETUP options, and data availability. The following fields of interest can be shown.

Table 42. User profile detail display - Connect group field values

Field	Description
Group	The groups the user is connected to
Auth	Connect authority
R	Indication whether this connect is revoked. This value takes into account any revoke and resume dates and the database *dumpdate*.
SOA	Indication whether user has the group SPECIAL, OPERATIONS, or AUDITOR attributes.
AG	Settings used for new data set or resource profiles created while the user is logged on with this group as the current connect group. **A** for ADSP is only used if the system-wide SETROPTS ADSP option has also been set. It controls whether data set creation automatically creates a discrete data set profile. The use of this attribute is deprecated. The G for GRPACC regulates whether the group must be added with UPDATE access to new group DATASET profiles.
Uacc	Default universal access for new dataset / resource profiles created while the user is logged on with this group as the current connect group.
Revokedt	Revoke date of connect
Resumedt	Resume date of connect
InstData	Installation data field of the group

System access fields

Field	Description
Revoked (can be by date)	Whether the user is in revoked status at the time of the database unload. This value is determined based on the revoke and resume dates for the user schedule.

Field	Description
Inactive, revoked or pending	This field shows *Yes* if the user ID cannot logon because of inactivity. It can be pending revoke, or already revoked (if the user has already tried to logon).
Days of week user can logon	1letter per day of the week, starting with Sunday. This field contains *SMTWTFS* if the user can logon on any day of the week.
Time of day user can logon	Indicates when a user can logon. The value can be blank if the logon time is not restricted, or a time range *HHMM:HHMM* if there is a restriction on the local time of day.
Date user will be revoked	The revoke date for the user ID.
Date user will be resumed	The resume date for the user ID

Statistics section

Field	Description
Creation date	This is the date that the profile was created.
Last RACINIT current connects	The last RACINIT logon or job initiation date with any of the current Connects for the user. This value is the last logon date if no connects have been removed. In that case it is often more accurate than the last use date.
User's last use date	The last use date. This value is usually the last RACINIT date, but it is also updated for certain user profile updates
User's last use time	The time of day of the last use. See also **User's last use date**.

Password fields

Field	Description
Has a password	This flag field indicates that the user can use a password to logon.
Expired password	This field contains *Yes* if the password is currently expired, which means that the user must change the password at the next login.
Password changed date	The date of the last password change
Password expiration date	The expiration date for the user password. The user must change the password when logging in on or after this date.
Old passwords present #	Number of previous passwords.
Failed password attempts #	Contains the number of failed passwords attempts since the last successful logon.
Password interval	The current password interval value. See the **Password interval in effect** field description for the value that is currently used by the system.
Password interval in effect	The password interval for the user ID that is currently active in the system (in days, or blank for NOINTERVAL). This value is also influenced by the SETROPTS INTERVAL setting.
Mixed case password	This flag field indicates that password checks for the user are case-sensitive.

Field	Description
Password disabled PROTECTED	Shows *Yes* if the user cannot be used with a password or revoked due to invalid passwords.
Has a password envelope	This flag field indicates that the user profile contains a password envelope with a two-way encrypted form of the password.

Password phrase

Field	Description
Has a password phrase	This flag field indicates that the user can use a password phrase to logon.
Expired password phrase	This field contains *Yes* if the password phrase is currently expired. If it is expired, the user must change the password at the next login.
Password phrase change date	The date of the last password phrase change.
Password phrase expiry date	The date the user password phrase expires. The user must change the password phrase when logging in on or after this date.
Old pass phrases present #	Number of previous password phrases.

Mandatory Access Control fields

Security label	Contains the default security label used in Mandatory Access Control decisions (B1 security).
Categories list	Lists all security categories that the user is permitted to read.

Privileges fields

Security admin SPECIAL	Contains *Yes* if the user has system-wide SPECIAL authority, which is usually an attribute that applies to a a central security administrator.
DASD administrator OPERATIONS	Contains *Yes* if the user has system-wide OPERATIONS authority, which means that the user ID can be used for changing almost any data set and for performing DASD management operations.
Global audit set/list AUDITOR	Contains *Yes* if the user has system-wide AUDITOR authority, which indicates that the user can review all security settings and request audit logging.
Class authority	The names of the general resource classes that the user can define new profiles for, or refresh profile caches in-storage.

Safeguards

Ignore UACC/Glob/* RESTRICTED	This field indicates whether user ID has the RESTRICTED attribute. If the value is *YES*, the UACC, global access, and ID(*) permits do not apply.
Log all user actions UAUDIT	This field contains *YES* if the user has the UAUDIT attribute. This attribute specifies all actions that are logged to SMF.

RACLINK section

Field	Description
input field	You can use the input field for a RACLINK entry to manage RACLINK associations. This field accepts the following line commands: **A** (Approve), **C** (Copy), **D** (Delete), or **I** (Insert) a RACLINK. For details, see "RACLINK fields" on page 79.
Linked node.user	Partner user ID at the specified node that this user is linked to through a `RACLINK` association. Authorized users can edit this field to change the value. Specify the value using the following syntax: `[node].user` The *node* can be either empty or a node name. The *user* is the `userid` for a valid user profile. Both values can be a maximum of 8 characters.
Type	Specifies the type of association between user IDs. Authorized users can edit this field to change the value. The following values are accepted. • *P*, *Peer*, or blank specifies peer association between users, with or without password synchronization. • *Managed* association. Password synchronization is not permitted.
Stat	Link status. This value is normally blank which indicates an approved status. However, the value can also be *Err* in case of an error, or *Pend* if pending approval. If the status is Pend, the association record can be approved using the **A** line command. For details, see "RACLINK fields" on page 79.
Pwd	Password synchronization flag, either *Sync* (active) or blank. Authorized users can edit this field to change the value. This field is only meaningful for RACLINK associations with `Type=Peer`. The field can have the following values: • *S* or *Sync* specifies association with password synchronization. • Leaving the field blank specifies association without password synchronization.
Defined (GMT)	Timestamp when link was defined.
Approved (GMT)	Timestamp when link was approved
Creator	User that created the link

Additional, optional properties

Digital certificate labels	List of associated digital certificates by label
Digital certificate names	List of associated digital certificates by name. Each entry lists the **Serial Number** and **Distinguished Name** for the Issuer, separated by a dot.
Certificate filter label	List of labels describing the digital certificate filters that map to this user ID.
Identity mapping label	The labels for the identity mappings to this user ID.

Identity mapping filter	The identity filter for the identity mappings to this user ID. The value can be in X.500 format.
Identity mapping registry	The registries for the identity mappings to this user ID.
Mapping profile label	Mapping profile name.
Audit concern	A concatenation of audit concerns for the user ID.
UsrNm	The names of the `userdata` fields, excluding those fields used by `CKGRACF`.
Flg	Flag associated with the `userdata` field
UsrData	Contents of the `userdata` field
CKGRACF authority requirement	The authority required to change this USER profile via `CKGRACF` (SINGLE, DOUBLE or TRIPLE), that is, the number of administrators who must sanction a command.
Scheduled events	The events making up the schedules deciding when the user can enter the system
Commands requiring administrator action	The commands that have not been fully authorized yet as per the `CKGRACF` authority requirement as specified in the **CKGRACF authority requirement** or through the system-wide default.
Inactive commands	Requested commands that were not fully authorized before they expired were withdrawn or denied. Inactive commands are listed as part of the audit trail.
Commands that have been executed	Commands that were fully authorized and run. These commands are included in the audit trail.
Other CKGRACF data	`Userdata` fields used by `CKGRACF` for other purposes. For user profiles, this value only shows the presence of a default password.

For more information, see the following topics:

- "RA.2 QUEUED - Queued commands" on page 185
- "MR - CKGRACF mulitple authority requirement" on page 63
- "MS - CKGRACF revoke/resume schedules" on page 64
- "P - Change password and resume user" on page 67

Additional selection - Other fields

If you check the 'Other fields' option on the primary selection panel, the advanced selection panel shown in Figure 78 on page 99.

```
 Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                        zSecure Suite - RACF - User Selection
Command ===>
Users like C##QA0*
Specify additional selection criteria:
Selection by date
Last logon/connect. __   ________________      (operator: < <= > >= = <> ¬= )
Last logon/update . __   ________________      (date: yyyy-mm-dd, ddMMMyyyy
Password changed  . __   ________________       NEVER, DUMPDATE, DUMPDATE-nnn,
Pass phrase changed __   ________________       DUMPDATE-INACTIVE, TODAY,
Creation date . . . __   ________________       TODAY-nnn, TODAY-INACTIVE)
Revoke date . . . . __   ________________

Logdays selection
_  Sun     _  Mon     _  Tue     _  Wed     _  Thu     _  Fri     _  Sat

Miscellaneous fields
Password interval . __ ___      (operator+number or Y/N)  / Effective only
Schedule name . . . ________    (schedule name or filter)
Complex . . . . . . ________    (complex name or filter)
```

Figure 78. Advanced user selection

Use this selection panel to specify a comparison criterion using the last connect date, last use date, last password change date, creation date, or revocation date, and to select on the presence or absence of certain attributes. The password interval field can be used either for a comparison or as an attribute that indicates if the users have any interval or NOINTERVAL.

The following advanced selection criteria are supported:

Table 43. Advanced user selection criteria

Selection Criteria	Description
Last logon/connect	Test the last connect RACINIT date, use with comparison operators, or NEVER. This value is the last logon date if no connects have been deleted.
Last logon/update	Test the date of the last RACINIT or update, use with comparison operators, or NEVER. This value can be more recent than the last logon date if the user profile has been updated.
Password changed	Test the date the password was last changed, *NEVER*, or < DUMPDATE-*nn* identifies users that have not changed their password in the last *nn* days.
Pass phrase changed	Test the date the password phrase was last changed, NEVER, or < DUMPDATE-*nn* to find users that have not changed their password phrase in the last *nn* days.
Creation date	Test the day the user was defined to RACF.
Revoke date	Revoked explicitly, or to be revoked on the specified date.
Logdays selection	Selects user IDs based on days they can logon (LOGDAYS). You can specify the following values. *Y* for all user IDs that are permitted to logon on the selected day. You can specify *S* or / instead of *Y*. *N* - for all user IDs that are not permitted to logon on the selected day blank - no selection is performed for this day

Table 43. Advanced user selection criteria (continued)

Selection Criteria	Description
Password interval	Test the password interval length. Specify *Y* to select only users with an expiring password. Specify *N*to select only users with a non-expiring password. Leave this field blank to disregard the password interval when making selections.
Effective only	When this option is selected, the value entered for the password interval (PASSINT field in the USER profile) is compared to the value of the SETROPTS PASSWORD(INTERVAL()) setting and the smaller value is used as the effective password interval. If the value of the effective password interval is smaller than the PASSWORD(MINCHANGE()) value, the PASSWORD(MINCHANGE()) value becomes the effective password interval. **Note:** The option has no effect on userids with passwords that cannot be changed; for example, userids assigned the PROTECTED attribute.
Schedule name	CKGRACF schedule name or a filter.
Complex	In a complex with this name, or a matching complex if a filter is used.

It is possible to test on the contents of DATE fields using the comparison operators listed on the panel. The operators have the following meaning:

Table 44. Date comparison operators for advanced user selection criteria

Operator	Description
<	Date is before the specified value.
>	Date is after the specified value.
=	Date is at the specified value.
<> or ¬=	Date is not at the specified value.

Table 45 lists the valid formats for a DATE comparand. You can specify the format in either upper or lower case.

Table 45. Date comparand formats for advanced user selection criteria

Date comparand	Description
ddmmmyyyy	**Example:** 01JAN1998. Valid month codes are *JAN*, *FEB*, *MAR*, *APR*, *MAY*, *JUN*, *JUL*, *AUG*, *SEP*, *OCT*, *NOV*, *DEC*.
yyyy-mm-dd	**Example:** 1998-12-31. This is the ISO date format.
NEVER	Indicates that the field has never been set, or has been reset to its initial state. For example, Last logon = NEVER looks for users who have never logged on (LJDATE). *NEVER* is only useful when used with the = operator.
DUMPDATE	The date when the UNLOAD you are processing was created or, if you are working from the active RACF database, today.

Table 45. Date comparand formats for advanced user selection criteria (continued)

Date comparand	Description
TODAY	Keyword to represent the current date.
DUMPDATE-nnn *TODAY-nnn*	*nnn* days before *TODAY* or *DUMPDATE*. If you are working with an UNLOAD data set created in the past, do not use the *TODAY* value in your compare specification.
DUMPDATE-INACTIVE *TODAY-INACTIVE*	The SETROPTS INACTIVE interval before *DUMPDATE* or *TODAY*.
DUMPDATE+nnn TODAY+nnn	*nnn* days after *TODAY* or *DUMPDATE*. This value is useful for finding REVOKE actions.

Figure 79 shows a query to select users that had group authorization SPECIAL and OPERATIONS attribute in any group, no password interval, and had not changed their passwords for at least 60 days since the date the currently selected database image was captured (*dumpdate - 60*).

Connect authority . >=_  2_  1. Use   2. Create   3. Connect  4. Join
```

Figure 80. User attribute selection

Use this selection panel to select on the presence or absence of certain attributes. Some of the attributes are grouped. You can specify whether you want them combined with AND or OR logic within the group. All resulting clauses are furthermore combined with AND logic.

Table 46 lists the advanced selection criteria that are supported. For each selection criteria field, you can specify the following values:

- *Y* or / selects based on the criteria being true.
- *N* selects based on the criteria being false.
- If you leave the selection field blank, that selection criteria is ignored during the selection process.

Table 46. Advanced selection criteria for User attributes

Field	Description
System-wide and group authorizations: Special, Operations, Auditor, Class auth	Selects record based on the system-wide and group authorization attributes: SPECIAL, OPERATIONS, and AUDITOR.
Logon status: Revoked	Selects based on whether the ID has been revoked.
Logon status: Inactive	Selects based on whether the ID is inactive. Inactive users are those who have been logged on for too long based on the setting specified by SETROPTS INACTIVE() option.
Logon status: Protected	Selects based on whether a user ID has the PROTECTED attribute.
Logon status: Passw expired	Selects based on whether the password for the user ID is expired.
Logon status: Revoked group	Selects based on whether the user has a revoked group connect.
Logon status: Certificate	Selects based on whether the user has a security certificate.
Logon status: Pass phrase	Selects based on whether the user requires a password phrase.
Logon status: Phrase expired	Selects based on whether the user password phrase is expired.

Table 46. Advanced selection criteria for User attributes (continued)

Field	Description
Logon status: When day/time	Selects based on whether the user has logon restrictions by date or time.
User properties: Has RACLINK	Selects based on whether the user ID is linked to another user ID or database.
User properties: Restricted	Selects based on whether a user ID has the `RESTRICTED` attribute. Non-restricted users have access to the UACC, global, and `ID(*)` resources.
User properties: User audited	Selects based on whether a user is being audited which is indicated by the status of the UAUDIT attribute.
User properties: Mixed case pwd	Select based on whether a user ID has a mixed case password.
CKGRACF features: Queued cmds	Select based on whether the command queue contains commands for the user ID.
CKGRACF features: Schedules	Select based on whether a user ID has any scheduled events.
CKGRACF features: Userdata	Selects based on whether user has any non`CKGRACF userdata`.
CKGRACF features: MultiAuthority	Selects based on whether a user ID has dual or triple authority requirements.
Connect authority	Selects a user based on the specified connect authority. Only users that have at least one group connection that satisfies the authority-level comparison condition will be shown.

In Figure 81, a query is shown after users that had group-special `OR` group-operations authorization (in any group).

```

Figure 82. User Overview panel

When you enter the / command on any line, a pop-up opens to describe the available line commands. You must scroll up and down to see all available line commands. The line commands available for a USER profile display are shown in the Table 47.

Table 47. Line commands for User profile display

Command	Meaning	Explanation
A	Authorization (permits and scope)	"RA.3.4 Permit/Scope - Report access of a user or group" on page 207
AC	Access Check for user ID on one profile	"RA.1 ACCESS - Access Check" on page 184
C	Copy user ID	"C - Copy" on page 55
CO	Add connect	"CO - Add connect" on page 57
D **DD**	(Prepare actions for) delete user ID, or delete a non-base segment	"D - Delete" on page 58
E	Display event logging	"E - Event" on page 59
L	RACF `listuser` all command	The output of the `listuser` command is presented in a browse panel.
M	Move user from group (to another)	"M - Move a user to another group" on page 60
MI	Manage user ID-information	"MI - Manage information" on page 61
ML	Manage logon-information	"ML - Manage logon information" on page 61
MR	Manage CKGRACF authority requirements	"MR - CKGRACF mulitple authority requirement" on page 63
MS	Manage CKGRACF revoke/resume schedules	"MS - CKGRACF revoke/resume schedules" on page 64
MT	Manage TSO-information	"MT - Manage TSO information" on page 66
MU	Manage installation-defined USERDATA	"RA.3.9 USERDATA - User data management" on page 219
P	Change password and resume	"P - Change password and resume user" on page 67
PE	Add or delete permit	"PE - Add or delete permit" on page 69
R **RR**	Recreate user ID	"R - Recreate a profile" on page 70
S	Show additional information	"S - Select" on page 72

Table 47. Line commands for User profile display (continued)

Command	Meaning	Explanation
SE	Show application segments	"SE - Show application segments" on page 72 and "Application segments" on page 106.
SR	Show all relevant information	"SR - Show all Relevant information" on page 73
TR	Trust bestowed on user ID	"TR - Trust bestowed on userid" on page 74
X **XX**	Exclude user ID from FORALL processing	"X - Exclude profile line command" on page 74
Z **ZZ**	Select user ID for FORALL processing	"Z - Select a profile" on page 74
34	Dataset List Utility	"34 - Data set list utility" on page 74

The line commands available on the detail display differ per field:

- For the connect groups, the line commands **L** (List), **C** (Copy) and **D** (Delete) are supported. These commands issue the RACF `listgrp`, `connect`, and remove commands. See "Connect detail view" on page 77.
- For digital certificates, the line commands **L** and **D** are supported, resulting in different forms of the RACDCERT command. See "Digital Certificate detail view" on page 78.
- For RACLINK associations, the line commands **A** (Approve), **C** (Copy), **D** (Delete), **I** (Insert). See "RACLINK fields" on page 79.
- For installation-defined `userdata` fields, the line commands **C** (Copy) and **D** (Delete) are supported, resulting directly in CKGRACF commands. The **I** (Insert), **R** (Repeat) and **S** (Select) commands are also supported. For more information about CKGRACF `userdata` fields and supported line commands, see See "USR fields" on page 78.
-

  "Access List detail view" on page 75

  "Connect detail view" on page 77

  "Data set detail view" on page 78

  "Digital Certificate detail view" on page 78

  "USR fields" on page 78

  "RACLINK fields" on page 79

Add new user or segment

You can add a new, generic user profile, or empty segment to the current system with the **Add new user or segment** option on the RACF User Selection panel ("RA.U USER - User information" on page 87).

You can also add a new user by copying an existing one. For details, see "C - Copy" on page 55. If you want to add a dataset profile or segment on another system, you must use a batch job.

Use the following procedure to add a new user profile or segment from the RACF User Selection panel.

1. On the RACF User Selection panel (Figure 72 on page 87), type a / or *S* in the **Add new user or segment** field.

2. Press **Enter** to open the User Add panel.

```
   Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - RACF - User Add
Command ===> ____________________________________________________________

Userid  . . . . . . C##QA99_ (required)
Default group . . . C##QA___ (required for new userid)
Password  . . . . .          . . .          (twice, required for new userid)
Owned by  . . . . . C##QA___ (may also be set in the follow on update dialog)
Password phrase . . ____________________________________________________
_____________________________________ (9-100 chars, in single quotes)

/   Define new userid

_   Add CICS segment                  _   Add NDS segment
_   Add CSDATA segment                _   Add NETVIEW segment
_   Add DCE segment                   _   Add OMVS segment
_   Add DFP segment                   _   Add OPERPARM segment
_   Add EIM segment                   _   Add OVM segment
_   Add KERB segment                  _   Add PROXY segment
_   Add LANGUAGE segment              _   Add TSO segment
_   Add LNOTES segment                _   Add WORKATTR segment
```

Figure 83. ADD USER panel

3. On the Add panel, you can add a new user profile, add an empty segment, or add a combination of a user profile and segment. For information on performing these tasks, see the ISPF panel help.
4. After specifying the field information, press **Enter** to the immediately add the user profile or segment on the system where you are logged on.

   The RACF command response is only shown if there is a nonzero return code.

Notes:

1. Your ISPF profile stores the default group and owner based on previous additions for users that do most of their additions in the same group. The format of the display is the same as the detail display described in "User profile detail display" on page 92.
2. Security zSecure requires users to type a new password twice for added security.
3. Users cannot specify a password equal to the user or equal to the default group.
4. After the addition operation has successfully completed, a panel opens with the new user profile or segment shown with modifiable fields for further customization. The format of this panel is the same as the detail display panel described in "User profile detail display" on page 92.

Application segments

You can use the **Show segments** option or the **SE** action command to view the application segments. For details about each segment and the information provided, select the following links.

CICS segment

The CICS segment stores CICS operator information for a CICS terminal user. Table 48 describes the overview and detail fields included for the segment.

Table 48. CICS segment

Overview field	Detail field	Explanation
Oid	**Operator identification**	Operator identification code
#Cl	n/a	The number of operator classes
Cls	**Operator class**	Operator class value (a number in the range 1 to 24). This value is a repeated field. To see all values, go to the detail display.
Pty	**Operator priority**	Operator priority
TmOut	**Terminal time-out value**	Terminal time-out value (in minutes)
Frc	**XRF Re-signon option**	XRF option for signing back on. This value indicates if CICS signs the operator off after an XRF takeover).
#TK	n/a	Number of Transaction Security Level Keys
#RK	n/a	Number of Resource Security Level Keys
n/a	**Resource SecurityLvl keys**	Resource Security Level Keys
n/a	**Transaction SecurityLvl keys**	Transaction Security Level Keys

CSDATA segment

The `CSDATA` segment stores custom defined profile fields. To add new fields to user profiles, use the `RACF CFIELD` class to define the new fields and labels you want to use for them.

The detail display shows the custom data. The RACF list header is followed by the value formatted according to the type. The value of the custom data is modifiable. Table 49 lists the action commands that can be performed on a custom data entry.

Table 49. CSDATA segment (custom data) action commands

Command	Action
C	Copy custom data. This action opens a panel for specifying the target profile destination for the copied data.
D	Delete custom data.

Table 49. CSDATA segment (custom data) action commands (continued)

Command	Action
I	Insert custom data. This action opens a panel on which you can select an entry name from a list of all defined custom fields. After you select a field, another panel opens on which you can enter the value for the new entry.
R	Recreate custom data. This action generates a RACF command that creates an exact copy of the entry.
S	Select or Modify custom data. This action opens a panel on which you can modify the custom data.

DCE segment

The DCE segment stores DCE (Distributed Computing Environment) info for RACF user IDs. Table 50 describes the overview and detail fields included for the segment.

Table 50. DCE segment

Overview field	Detail field	Explanation
DCE UUID	**DCE UUID**	DCE Universal Unique Identifier
LgA	**DCE Autologin**	Autologon requested.
DCE name	**DCE username**	DCE principal name for the RACF user
DCE homecell	**DCE homecell**	DCE cell for the RACF user
DCE homecell UUID	**DCE homecell UUID**	DCE Universal Unique Ident. in home cell

DFP application segment

The DFP segment stores DFP (Data Facility Product) defaults for RACF user IDs.

Table 51 describes the overview and detail fields included for the segment.

Table 51. DFP segment

Overview field	Detail field	Explanation
MgmtClas	**DFP - Management Class**	The management class
StorClas	**DFP - Storage Class**	The storage class
DataClas	**DFP - Data Class**	The data class
DataAppl	**DFP - Data Application**	The data application

EIM segment

The EIM segment stores Enterprise Identity Manager information for RACF user IDs.

Table 52 describes the overview and detail fields included for the segment.

Table 52. EIM segment

Overview field	Detail field	Explanation
LDAP Profile	**LDAP Profile**	Name of a profile in the LDAPBIND class which contains the name of an EIM domain.

KERB segment

The KERB segment stores Kerberos information for RACF user IDs.

Table 53 describes the overview and detail fields included for the segment.

Table 53. KERB segment

Overview field	Detail field	Explanation
Kerberos name	**Kerberos name**	Kerberos principal name.
MaxTktLife	**Maximum ticket life**	Maximum ticket life for this user in seconds.
Encryption	**Supported encryption types**	Types of encryption that can be used by this user.
EnTp	**Used encryption type**	The encryption type that has been used.
Kfm	**Password is Passphrase**	Indicates whether the password or passphrase was used to generate the Kerberos key.

LANGUAGE segment

The LANGUAGE segment stores the preferred national languages for the user.

Table 54 describes the overview and detail fields included for the segment.

Table 54. LANGUAGE segment

Overview field	Detail field	Explanation
NL1	**User's primary language**	User primary language
NL2	**User's secondary language**	User secondary language

LNOTES segment

The `LNOTES` segment is used to specify z/OS Lotus® Notes® information.

Table 55 describes the overview and detail fields included for the segment.

Table 55. LNOTES segment

Overview field	Detail field	Explanation
Notes short name	n/a	The Lotus Notes for z/OS short user name associated with the RACF `userid`.

NDS segment

The NDS segment specifies Novell Directory Services information.

Table 56 describes the overview and detail fields included for the segment.

Table 56. NDS segment

Overview field	Detail field	Explanation
Uname	**NDS username**	The Novell Directory Services user name associated with the RACF user ID.

NETVIEW segment

The `NETVIEW` segment stores `NETVIEW` operator information.

Table 57 describes the overview and detail fields included for the segment.

Table 57. NETVIEW segment

Overview field	Detail field	Explanation
Console	**Default console name**	Default console name
Rcv	**Receive undelivered messages**	Receive unsolicited messages
Adm	**Admin auth Graphic Mon Fac**	Admin authority for the Netview Graphic Monitor Facility
#Cl	n/a	Number of scope classes
#Dm	n/a	Number of cross-domain authorities
Control	**Scope of control**	Cross-domain logon authority
Cls	**Operator class**	Scope class. Number from 1 to 2040. To see all values, go to the detail display.
Dom.	**Cross-domain authority**	Cross-domain authorities. To see all values, go to the detail display.
Initial command list	**Initial command list**	Initial command to run whenever the operator logs on to `NETVIEW`.

OMVS segment

The OMVS segment stores UNIX System Services information.

Table 58 describes the overview and detail fields included for the segment.

Table 58. OMVS segment

Overview field	Detail field	Explanation
Uid	**UNIX user (uid)**	Numeric UNIX `uid` (0 = root authority). When fields are modifiable (overtypeable), appending the number with an S (*`1001S`*) adds the SHARED command keyword. You can also specify AUTO, which results in addition of the AUTOuID command keyword. The SHARED and AUTOUID command keywords are available in z/OS 1.4 or with APAR OW52135.
Home directory	**UNIX home path**	UNIX account home directory
Initial program	**Initial program**	UNIX account initial program
AS maxsize	**Max. address space size**	Maximum address space region size (bytes)
CPU max	**Maximum CPU time**	Maximum CPU time for process (seconds)
Files	**Max. files open per proc**	Maximum number of open files (3..262,143 (pre-z/OS V1R7) or 524,288 (z/OS V1R7 and up))
MxMemMap	**Max. data space for mapping**	Maximum data space pages memory mapping
Procs	**Max. nr. of active procs**	Maximum number of processes (3..32767)
Thread	**Max. nr. of active threads**	Maximum number of threads (0..100000)
MemLimit	**Maximum non-shared memory**	Maximum number of bytes of non-shared that can be allocated by the user.

Table 58. OMVS segment (continued)

Overview field	Detail field	Explanation
ShMemMax	**Maximum shared memory**	Maximum number of bytes of shared that can be allocated by the user.

OPERPARM

The OPERPARM segment stores extended MCS console information session information.

Table 59 describes the overview and detail fields included for the segment.

Table 59. OPERPARM segment

Overview field	Detail field	Explanation
CmdSys	**System to send commands to**	The name of the system the operator is connected to for command processing
OpAut	**Console authority**	The command authority in effect for the operator.
L	**Command response logging**	Command response logging on hardcopy
M	**Migration id to be assigned**	Migration console ID to be assigned setting
U	**Receive undelivered messages**	'Undeliverable' messages to be received setting
A	**Receive msgs automated by MPF**	Messages marked for automation in MPF are to be received at the console
H	**Receive hardcopy messages**	This field indicates whether the operator receives messages that are directed to hardcopy
I	**Receive messages for ID 0**	This field indicates whether the operator receives messages directed to console ID 0, the internal console.
u	**Receive messages unknown IDs**	This field indicates whether the operator receives messages directed to unknown console IDs
DOM	**Delete operator messages type**	Delete operator message requests to be received setting
Message level	**LEVEL of msgs to be received**	Level of messages to be received
Key	**KEY keyword of D,CONSOLES,KEY**	KEY keyword for D CONSOLES,KEY
Mon	**Events to be monitored**	Events to be monitored
Stor	**STORAGE in MB for msg queuing**	Maximum storage for message queuing (in MB)
Mform	**Message format**	Message format
Altgrp	**Alternate console group**	Alternate console group
Routcde	**ROUTCODEs for msg reception**	Routecode of message to be received
Mscope	**Mscope systems**	Mscope systems. To see all values, go to the detail display.

OVM segment

The OVM segment stores Unix System Services information.

Table 60 describes the overview and detail fields included for the segment.

Table 60. OVM segment

Overview field	Detail field	Explanation
Uid	OpenVM user (uid)	Numeric Unix uid value
Home directory	OpenVM home path	UNIX account home directory
Initial program	Initial program	UNIX account initial program
File system root	UNIX file system root	Path name for the file system root

Proxy segment

The PROXY segment is only valid for the FACILITY and LDAPBIND classes. It is stores LDAP proxy server information.

Table 61 describes the overview and detail fields included for the segment.

Table 61. PROXY segment

Overview field	Detail field	Explanation
LDAP host	**LDAP host**	Host of LDAP server to contact
Bind name	**Bind distinguished name**	Bind information for LDAP server being contacted

TSO segment

The TSO segment stores Time Sharing Option settings.

Table 62 describes the overview and detail fields included for the segment.

Table 62. TSO segment

Overview field	Detail field	Explanation
DfltUnit	**Default unit name**	Default unit name for DASD allocations
DftKB	**Default logon region size (KB)**	Default region size in KB.
MaxKB	**Maximum region size**	Maximum region size in KB.
H	**Default held sysout class**	Default held sysout class
J	**Default job class**	Default job class
M	**Default message class**	Default message class
S	**Default sysout class**	Default sysout class
Destinat	**Destination identifier**	Default destination
ProcName	**Default logon procedure**	Default logon procedure
Acctnum	**Default account number**	Default account number
Opt	**Mail/Notice/Recon/ OID options**	Mail/Notice/REconnect/ OIDcard options

Table 62. TSO segment (continued)

Overview field	Detail field	Explanation
Prf	**Performance group**	Performance group
Prefix	**UPT control block data**	TSO UPT profile settings: TSO dataset prefix
PI?MOWRL	**UPT control block data**	TSO UPT profile settings: *P* Prompt *I* Intercom *?* Pause *M* Msgid *O* Mode *w* Wtpmsg *R* Recovery *L* Varstorage
Data	**Site data TSO user (2 byte)**	TSO user data. This value is carried over from SYS1.UADS–2 bytes printed in hexadecimal.
Command	**Default command**	Default command

WORKATTR segment

The WORKATTR segment specifies user-specific attributes of a unit of work.

Table 63 describes the overview and detail fields included for the segment.

Table 63. WORKATTR segment

Overview field	Detail field	Explanation
Name (workattr)	**User name for SYSOUT**	User name for SYSOUT
Dept	**Department for delivery**	Department for delivery
Building	**Building for delivery**	Building for delivery
Room	**Room for delivery**	Room for delivery
Account	**Account number**	Account number
n/a	**SYSOUT address line 1**	Indicates SYSOUT delivery address line 1.
n/a	**SYSOUT address line 2**	Indicates SYSOUT delivery address line 2.
n/a	**SYSOUT address line 3**	Indicates SYSOUT delivery address line 3.
n/a	**SYSOUT address line 4**	Indicates SYSOUT delivery address line 4.

Print format

To produce a printable report instead of an interactive display, select the *Print format* option. When this option is selected, other print-related option fields are activated. Use *Customize title* to specify a title for the two header lines to be printed on each page in addition to the main report title. If *Background run* is selected together with *Print format*, then a batch job is submitted to perform the query. This flag setting is saved in your ISPF profile and is shared between all RA options

showing it. To send the report through email, select the *Send as email* option. You are prompted to supply the email options. By default the report is shown in a tabular form for improved readability, formatted into 132 columns. Tag *Full page form* if you would rather have more details. Tag *Narrow print* to force it into 79 columns. You can change the sort order of the results by selecting the *Sort differently* option.

If *Sort differently* is selected, a sort order panel opens for each segment type to be shown. Figure 84 shows a sample of the Sort order panel for the base segment.

```
  Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - RACF - User Sort order
Command ===> ____________________________________________________________
All users
Specify up to 3 fields to act as alternate base segment sort order
Select with 1 or / and optiopnally 2, 3
_ Userid
_ Name
_ Installation data
_ Owner
_ Default group
1 Last logon/connect date
_ Password interval (descending)
_ By audit priority (descending)
```

Figure 84. Segment - Sort order panel

In the sort order panels, you can specify up to three sort keys by entering 1, 2, or 3 in front of the sort criteria. If you want to sort on just one column, it is also possible to use a / instead of 1.

Figure 85 shows an example of wide tabular print output of user profile base segments, sorted by last connect date.

RA.G GROUP - Group information

The Group information panel provides access to simple selection functions for groups. Using these functions, you can do things like the following:

- Add a new group or segment. See "Add new group or segment" on page 127.
- Specify selection criteria for GROUP profiles.

Only profiles that match **all** criteria are selected. In effect, all the search criteria are combined with AND logic.

The simple selection panel is shown in Figure 86 on page 118.

```
 Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                        zSecure Suite - RACF - Group Selection
Command ===> ____________________________________________   _  start panel

_   Add new group or segment

Show groups that fit all of the following criteria
Group id  . . . . . ________     (group profile key or filter)
Owner . . . . . . . ________     (group or userid, or filter)
Subgroup of . . . . C##B____     (group or filter)
With subgroup . . . ________     (group or filter)
Installation data . ____________________________ (data scan, no filter except *)

Additional selection criteria
_  Profile fields     _  Connect fields   _  Segment presence  _  Absence

Output/run options

   _  Print connects  _  Print names      _  Print subgroups
```

Figure 86. Simple group selection

The following selection criteria are available.

Table 64. Group selection criteria

Criteria	Description
Group Id	This group ID, or a matching ID if a filter is used.
Owner	If specified, groups are selected based on the OWNER value you specify. The owner can be a user or group. It is possible to use a filter.
Subgroup of	You can select an entity through its superior group. It is possible to use a filter to select an entity through more than one superior group.
With subgroup	You can select an entity through its subgroups. The select group is the superior group of the group you specify here. It is possible to use a filter to select an entity through more than one subgroup.
Installation Data	Data to scan for in the installation data field. You cannot use a filter except *, which means find any profile with installation data.

Additional selection criteria can be requested by selecting the following options.

Table 65. Additional Group selection criteria

Criteria	Description
Profile fields	When you select this option, another panel opens for selecting criteria based on profile field values. The selection panel is shown in "Additional selection - Profile fields" on page 120. If the field is not selected, the **Profile fields** selection criteria are not used but are saved for later use when you remain in **RA.G**.
Connect fields	Use this option to specify criteria to select based on d users. The selection panel is shown in "Additional selection - Connect fields" on page 121. If the field is not selected, those selection criteria are not used but are saved for later use when you remain in **RA.G**.

Table 65. Additional Group selection criteria (continued)

Criteria	Description
Segment presence	If this field is selected, criteria can be specified for the presence of application segments. A segment selection panel and a segment field selection panel are shown. Unless the output option **Show segments** has also been selected, these panels only show the base segment of groups that have the specific non-base segment. If the field is not selected, the selection criteria are not used but are saved for later use when you remain in **RA.G**.
Segment absence	If this field is selected, absence of a segment can be specified as an additional selection criterion. If the field is not selected, the selection criteria are not used, but are saved for later use when you remain in **RA.G**.

Table 66 lists the output and run options you can specify.

Table 66. Output and run options for Groups

Option	Description
Show segments	Show a selectable set of application segments for specifying select and exclude criteria based on segment field values. If this option is not selected, the segment subset is not used but is saved in your ISPF profile for later use. This flag setting is saved in your ISPF profile.
All	Select this option with *Show segments* to show all segments for the selected groups.
Expand universal	Select this option to request that the default connections to universal groups are shown for profiles with connect authority `USE` and no group special, operations, or auditor attribute. This setting implies a full database read. If **Print format** is also specified, the **Expand universal** option only has effect when **Print connects** is also specified or implied.
Specify scope	If this field is selected, you can limit the results to the scope of a user ID or group.
Print format	If this field is selected, results are in print format instead of ISPF display format. This flag setting is saved in your ISPF profile and is shared between all **RA** options showing it. The other print-related options only apply if **Print format** has been selected. See also “Print format” on page 129.
Customize title	If this field is selected together with **Print format**, you can change the subtitle for the selection. You can also add an extra title that is saved in your ISPF profile, including your company name, department, and phone number for example. This flag setting is saved in your ISPF profile and is shared among all **RA** options that include this field.
Send as email	If this field is selected along with **Print format**, then a panel opens for specifying the email address destination for the report. The email function does not work until you have configured the SMTP options with `SETUP OUTPUT`. This flag setting is saved in your ISPF profile and is shared by all **RA** options showing it.
Background run	If this field is selected together with **Print format**, then a batch job is submitted to perform the query. This flag setting is saved in your ISPF profile and is shared by all `RA` options showing it.

Table 66. Output and run options for Groups (continued)

Option	Description
Full detail form	If this field is selected together with **Print format**, forms (one subpage per group, separated by dashed lines) are used to include details. This selection implies selections for the **Print connects**, **Print names**, and **Print subgroups** options. This flag setting is saved in your ISPF profile. If you have requested segments, they are shown on the same page with the other group information. If the **Full detail form** field is not selected, each segment type is shown in its own tabular report. Sample output is shown in "Print format" on page 129.
Sort differently	If this field is selected together with **Print format**, then an alternate sort order can be selected. If you want to change the sort order in an ISPF display panel (**Print format** not selected), you can use the `SORT` primary command in the result panel. This flag setting is saved in your ISPF profile.
Narrow print	If this field is selected together with **Print format**, then the width of the page is limited to 79 characters, independent of the actual print file record length. If the field is not selected, then the page layout you specify must support a width of 132. However, the length can extend beyond that if the print file has a larger record length. This flag setting is saved in your ISPF profile and is shared by all panels showing this option.
Print connects	If this field is selected with **Print format**, then the connect entries are printed. The `Exact` format depends on the **Print names** and **Narrow print** settings. The default sort order (by descending access) can be changed by checking the **Sort differently** option. The **Print connects** option is automatically implied by **Full detail form**. If you want to limit the number of lines in the results, do not select the **Print connects** option. This flag setting is saved in your ISPF profile.
Print names	If this field is selected with the **Print format** and **Print connects**, then the connect entries are printed with names and installation data added. Only the first part of the installation data is printed, depending on the setting of option **Narrow print**. If **Narrow print** is selected, then the revoke and resume dates for connect entries are not visible in the report. This flag is implied by **Full detail form**. This flag setting is saved in your ISPF profile.
Print subgroups	If this field is selected with the **Print format** and **Print connects**, then the subgroups are listed. This flag setting is saved in your ISPF profile.

Additional selection - Profile fields

In the example shown in Figure 86 on page 118, the subgroups of *C##B* have been selected. If the option **Profile fields** has also been checked, the advanced selection panel shown in Figure 87 on page 121 opens.

```
 Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                        zSecure Suite - RACF - Group Selection
Command ===> ____________________________________________________________

Subgroups of C##B
Show groups that also fit all of the following criteria:
Selection by date
Creation date . . . __   ___________          (date: yyyy-mm-dd/ddMMMyyyy/
                                                    DUMPDATE/DUMPDATE-nnn/
                                                    TODAY/TODAY-nn/NEVER)

Miscellaneous fields
Complex . . . . . ________     (complex name or filter)
# connected users . >_  2___                 (operator: < <= > >= = <> ¬= )
# subgroups . . . . __  ____

Enter "/" to specify selection criteria
_  Universal group
_  Queued commands
_  Userdata
```

Figure 87. Advanced group selection

In this second panel, an additional selection criteria is specified to select only groups that have more than two connected users.

The following additional selection criteria are available on this panel:

Table 67. Additional group selection criteria

Criteria	Description
Creation date	Test the day the group was defined to RACF
Complex	In a complex with this name, or a matching complex if a filter is used.
# connected users	Test the number of connected users, with comparison operators. For universal groups, this number only includes the users with non-default connections. That is, users with a connect authority higher than USE or users with the group attributes `SPECIAL`, `OPERATIONS`, or `AUDITOR`.
# subgroups	Test the number of subgroups, with comparison operators.
Universal group	Show only groups with the UNIVERSAL attribute.
Queued commands	Show only groups with one or more commands queued.
Userdata	Show only groups with `userdata`.

Additional selection - Connect fields

In the example shown in Figure 86 on page 118, the subgroups of C##B that have more than two users have been selected. You can use **Connect fields** for specifying additional selection criteria based on Connect field values. When you select this option, the advanced selection panel shown in Figure 88 on page 122 opens.

```
 Menu   Options   Info   Commands   Setup

```

Figure 88. Group connect selection

Table 68 describes the following additional selection criteria on this panel:

Table 68. Group connection selection criteria

Criteria	Description
Connected user	Search for groups with the specified user ID on the connect list.
Connect authority	Test for the following connect authorities using comparison operators: `USE`, `CREATE`, `CONNECT`, or `JOIN` authority.

When performing these selections against groups with the `UNIVERSAL` attribute, the only connects considered are for groups that have either a connect authority higher than `USE` or the group attributes `SPECIAL`, `OPERATIONS`, or `AUDITOR`.

Table 69 describes the filtering options available on the Group Connection panel.

Table 69. Group connection output filtering options

Option	Description
User/authority Match selection above	You can limit the number of connects shown with a group to the ones that match the **Connected user** and **Connect authority** search criteria.
Default UACC	You can limit the number of connects being shown with a group to the ones that satisfy the comparison operator applied to the default universal access. The default UACC is only used when the user creates a profile in a class that has the ACEE setting as the default UACC. See the “STATUS AUDIT - RACF control” on page 266 CDT option.
Set of attributes	Use the operator to determine how the authorities relate to each other. Specify `OR` or `AND` to filter using combined attributes.
Special	Selects all connects that have Group Special authority. User IDs that have this authority can change, delete, and create any group-owned profile for a specific group.
Operations	Selects all connects that have Group Operations authority. User IDs that have this authority can alter group-owned data sets unless they are specifically on the access list.
Auditor	Selects all connects that have Group Audit authority.

Table 69. Group connection output filtering options (continued)

Option	Description
Revoked	Selects all Connects that are currently revoked, which includes the Connects that were revoked at the *dumpdate* for the security database. This value selects connect entries based on the values of the `revoke flag`, `revoke date`, and `resume date`.

Group profile tabular display

As a result of a query, a group list can be produced like the one shown in Figure 89. Fields that can be modified are shown padded with underline characters.

Figure 89. Group profile display

Table 70 describes the fields of interest on the Group Profile display panel.

Table 70. Group profile display important fields

Field	Description
Group	The name of the group.
Complex	The name of the complex.
SupGroup	The superior group.
X	Indicates an interruption in group ownership. A break occurs if the owner and superior group differ.
Owner	The owning user or group for a group profile.
Grps	The number of subgroups that have this group as superior group
Users	The total number of users connected to this group, even for `UNIVERSAL` groups.
Conn	The number of users connected to this group. For a group with the universal attribute, this field only counts users that have a group access level higher than the default level.
U	If a U is shown in this column, the group has the `UNIVERSAL` attribute.
nTU	For all connected users: no terminal access based on `UACC`.
Created	Creation date of this group
Pri	The relative audit priority for this group.
InstData	Installation data

Group profile detail display

Select any group on the group profile table display to see the detail view. You can select entries by putting the cursor on the first character of a row selection field and pressing **Enter**, or by explicitly typing S and pressing **Enter**.

Figure 90. Group Profile detail display

The fields shown on the Group Profile detail display panel depend on the SETUP configuration and data availability.

Identification fields. Table 71 describes the Identification fields.

Table 71. Group profile detail display - Identification fields

Field	Description
Identification	To the far right, the complex name is shown.
RACF group name	The RACF profile key.
Superior group	Lists the parent group for this group in the group tree followed by its installation data.
Owner	The owning user or group followed by the user name and the user or group installation data.
Installation data	Installation data field of the group.

Connect fields. Table 72 on page 125 describes these fields. If the current group has the UNIVERSAL attribute, you can control whether users with default connect attributes are shown by issuing the ACL UNIVERSAL and ACL NOUNIVERSAL primary commands.

Table 72. Group Profile detail display - Connect fields

Field	Description
User/grp	Users connected to the group
Auth	Connect authority
R	Indicates whether this connect is revoked. This setting is determined by considering any revoke and resume dates and the database `dumpdate`.
SOA	Indicates whether the user has the following group attributes: `SPECIAL`, `OPERATIONS`, or `AUDITOR`.
AG	Settings used for new data set or resource profiles created while the user is logged on with this group as the current connect group. The *A* for ADSP is only used if the system-wide SETROPTS ADSP option has also been set. It controls whether creation of a data set automatically results in creation of a discrete data set profile. Its use is deprecated. The G for `GRPACC` regulates whether the group must be added with UPDATE access to new group data set profiles
Uacc	Default universal access for new data set or resource profiles created while the user is logged on with this group as the current connect group.
Revokedt	Revoke date of connect
Resumedt	Resume date of connect
Name	Name of connected user
DfltGrp	Default group for the user
InstData	Installation data field of the user

Subgroup fields. Table 73 describes these fields.

Table 73. Group Profile detail display - Subgroup fields

Field	Description
Subgroup	The groups for which this group is the superior group
InstData	Installation data field of the subgroup

Safeguard fields. Table 74 describes these fields.

Table 74. Group Profile detail display - Safeguard fields

Field	Description
Terminal use authorization	Indicates whether Terminal use authorization is required for all connected users. If this option is selected, terminal access is not granted based on UACC.
Universal access authority	The default Universal Access Authority for the group profile.
Data set model profile name	Name of a discrete data set profile for modeling new `group-name` data sets.

Statistics fields. Table 75 on page 126 describes these fields.

Table 75. Group Profile detail display - Statistic fields

Field	Description
Creation date	The date that the profile was created.
Universal group	Whether this group has the UNIVERSAL attribute. With this attribute, there is no limit on the number of users that can connect to a group with default authorities.

Additional, optional properties. Table 76 describes these fields.

Table 76. Group Profile detail display - Additional, optional properties fields

Field	Description
Audit concern	A concatenation of audit concerns for the group.
UsrNm	The names of the `userdata` fields, excluding the fields used by `CKGRACF`.
Flg	Flag associated with the `userdata` field
UserData	Contents of the `userdata` field
CKGRACF authority requirement	Authority required to change this GROUP profile. Possible values are: SINGLE, DOUBLE or TRIPLE. These values represent the number of administrators who must sanction a command.
Timed commands waiting for execution	`P` indicates time commands that have been approved and are now waiting for the scheduled run date. `PR` indicates temporary commands that remain in this queue waiting for their reversal date.
Commands requiring administrator action	Commands that have not been fully authorized yet as per the value specified in the **CKGRACF authority requirement** field or based on the system-wide default value.
Inactive commands	Requested commands that were not fully authorized and then expired, were withdrawn, or were denied. These commands are included in the audit trail with others that were not run.
Commands that have been executed	Commands that were fully authorized and run. These commands are included in the audit trial.

For an explanation of the CKGRACF data, see "RA.2 QUEUED - Queued commands" on page 185 and "MR - CKGRACF mulitple authority requirement" on page 63.

Line commands for a group profile display

When you use **/** line command to ask which line commands are permitted, the following table is shown.

Table 77. Group profile display - Line commands

Command	Meaning	Explanation
A	Group authorization (permits and scope)	"RA.3.4 Permit/Scope - Report access of a user or group" on page 207
AC	Access check for group on one profile	"RA.1 ACCESS - Access Check" on page 184
C	Copy group ID.	"C - Copy" on page 55
CO	Add connect.	"CO - Add connect" on page 57

Table 77. Group profile display - Line commands (continued)

Command	Meaning	Explanation
D **DD**	Delete group, or delete a non-base segment	"D - Delete" on page 58
E	Display event logging.	"E - Event" on page 59
L	RACF `listgrp` all command	The results of the `listgrp` command is presented in a browse panel.
MI	Manage group information.	"MI - Manage information" on page 61
MR	Manage `CKGRACF` authority requirements	"MR - CKGRACF mulitple authority requirement" on page 63
MU	Manage installation-defined `userdata`	"RA.3.9 USERDATA - User data management" on page 219
PE	Add or delete permit	"PE - Add or delete permit" on page 69
R **RR**	Recreate group ID	"R - Recreate a profile" on page 70
S	Show additional information	"S - Select" on page 72
SE	Show application segments	"SE - Show application segments" on page 72 and "Application segments" on page 128.
SR	Show all relevant information	"SR - Show all Relevant information" on page 73
X **XX**	Exclude group ID from `FORALL` processing.	"X - Exclude profile line command" on page 74
Z **ZZ**	Select group ID for `FORALL` processing.	"Z - Select a profile" on page 74
34	Data Set List Utility	"34 - Data set list utility" on page 74

Add new group or segment

You can add a new group or segment to the current system with the **Add new group or segment** option on the RACF Group Selection panel (Figure 86 on page 118).

You can also add a new profile by copying an existing one. For details, see "C - Copy" on page 55. If you want to add a group or segment on another system, you must use a batch job.

Use the following procedure to add a new group or segment from the RACF Group Selection panel.

1. On the RACF Group Selection panel (Figure 86 on page 118), type a / or *S* in the **Add new group or segment** field.
2. Press **Enter** to open the Add GROUP panel.

```
 Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                        zSecure Suite - RACF - Group Add
Command ===> ____________________________________________________________

Group id  . . . . . ________     (required)
Superior group  . . C##C____     (required for define new profile)
Owner . . . . . . . =________    (userid, or better = to use superior group)

/   Define new GROUP profile              _  Universal group
_   Add CSDATA segment
_   Add DFP segment
_   Add OMVS segment
_   Add OVM segment
_   Add TME segment
```

Figure 91. ADD GROUP panel

3. On the Add panel, you can add a new group, add a segment to an existing group, or add a combination of a group and segment. For information on performing these tasks, see the ISPF panel help.
4. After specifying the field information, press **Enter** to the immediately add the group or segment on the system you are logged on to.

   The RACF command response is only shown if there is a nonzero return code.

Notes:

1. When the Add panel displays, the default superior group and owner are stored in your ISPF profile based on previous add group operations. This information is provided to support users that do most of their additions in the same group.
2. After the addition operation has successfully completed, a panel opens with the new profile or segments shown with modifiable fields for further customization. The format of this panel is the same as the detail display panel described in "Group profile detail display" on page 124.

Application segments

When the **Show segments** option is selected, or the **SE** action command is used, application segments are displayed.

The CSDATA segment stores custom defined profile fields. To add new fields to group profiles, use the RACF `CFIELD` class to define the new fields and labels you want to use for them.

The detail display shows the custom data; the RACF list header followed by the value formatted according to the type. The value of the custom data is modifiable. Table 78 lists the action commands that can be performed on a custom data entry.

Table 78. CSDATA segment (custom data) action commands

Command	Action
C	Copy custom data. This action opens a panel for specifying the target profile where the data is copied.
D	Delete custom data.
I	Insert custom data. This action opens a panel on which you can select an entry name from a list of all defined custom fields. After you select a field, another panel opens on which you can enter the value for the new entry.

Table 78. CSDATA segment (custom data) action commands (continued)

Command	Action
R	Recreate custom data. This action generates a RACF command that creates an exact copy of the entry.
S	Select/Modify custom data. This action opens a panel on which you can modify the custom data.

The DFP segment is used to store DFP (Data Facility Product) defaults for RACF groups.

Table 79. DFP segment

Field	Explanation
MgmtClas	The management class
StorClas	The storage class
DataClas	The data class
DataAppl	The data application

The group OMVS segment display shows the group ID for the UNIX System Services. When the `Overtype` function is active, you can append an *S* to the number (*1001S*) to add the `SHARED` command keyword. You can also specify AUTO, which results in addition of the `AUTOGID` command keyword. The `SHARED` and `AUTOGID` command keywords are available in z/OS 1.4 or with APAR OW52135.

The group OVM segment display shows the group ID for z/VM OpenExtensions.

The group TME segment detail display lists the role access specifications for the group in the Tivoli Management Environment. The segment display shows the number of specifications and the first specification.

Print format

To produce a printable report instead of an interactive display, select the **Print format** option. When you select this option, the other print-related options are available for selection. Select **Customize title** to specify two header lines to be printed on each page in addition to the main report title. To send the report through email, select the **Send as email** option. You are prompted to supply the email options. By default the report is shown in a tabular form for improved readability, formatted into 132 columns. Tag **Full page form** if you would rather have more details. Tag **Narrow print** to limit the page width to 79 columns. You can change the sort order of the results by selecting the **Sort differently** option. When you select this option, a sort order panel is shown for each segment type to be included in the report. Figure 92 on page 130 shows the sort panel for the base segment:

```
  Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                        zSecure Suite - RACF - Group Sort Order
Command ===> ____________________________________________________________
All profiles
Specify up to 3 fields to act as
alternate base segment sort order
Select with 1 or / and optionally 2, 3
_ Group name (default)
_ Grouptree traversal
_ Depth
_ Installation data
_ Owner
_ Superior group
_ Break in group scope
_ Number of groups (descending)
_ Number of users (descending)
_ Creation date (descending)
_ Terminal universal access
_ Universal access (descending)
_ By audit priority (descending)
```

Figure 92. Group sort order panel

In the sort order panels, you can specify up to three sort keys by entering *1*, *2*, or *3* in front of the sort criteria. If you want to sort on just one column, it is also possible to use a / instead of *1*.

Figure 93 shows an example report with wide tabular print format of group profile base segments, sorted by descending number of users.

RA.D DATASET - Dataset profiles

The Dataset profiles display shows profiles rather than the data sets protected by them. To find about protection for a particular data set, see "RA.3.1 Profiles - Profiles with their data sets" on page 196 and "RA.1 ACCESS - Access Check" on page 184

Simple selection functions

You can use the simple selection panel to add a new profile or segment or to select which profiles to view.

```
  Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                        zSecure Suite - RACF - Data set Selection
Command ===> ____________________________________________________   _ start panel

_   Add new DATASET profile or segment

Show dataset profiles that fit all of the following criteria
Dataset profile . . SYS1.**_____________________________________  1 1 EGN mask
Owned by  . . . . . ________     (group or userid, or filter)       2 Exact
High level qual . . ________     (qualifier or filter)              3 Match
Installation data . ____________________ (substring or *)          4 Any match

Additional selection criteria
/  Profile fields     /  Access list      _  Segment presence  _  Absence

Output/run options
_  Show segments      _  All              _  Enable full ACL   _  Specify scope
   Print format       _  Customize title  _  Send as email
   _  Background run  _  Full detail form _  Sort differently  _  Narrow print
   _  Print ACL       _  Resolve to users _  Incl operations   _  Print names
```

Figure 96. Simple dataset profile selection

For information on adding a profile or segment with the **Add new DATASET profile or segment** option, see "Add new DATASET profile or segment" on page 144.

Table 80 describes the available selection criteria.

Table 80. Data set selection criteria field descriptions

Selection criteria field	Description
Dataset profile	If the EGN mask option is selected: an EGN filter to select data set profiles can be used. You can use * in the first qualifier, *SYS*.** to see all z/OS profiles. If **Exact** is selected, you must specify the name of the data set profile in this field.
EGN mask/Exact/Match/ Any match	This field specifies the matching criteria. • **EGN mask** means the query interprets the profile name as an EGN filter (* and % characters are expanded). • **Exact** selects the exact RACF profile. • **Match** treats the profile field as a resource name and selects the profile that best matches the resource name. • **Any match** treats the profile field as a resource name and selects all profiles that match the resource name.
Owned by	Specify an OWNER name as a selection criteria. The owner can be a user or group.
High level qual	The first qualifier of the profile, modified by ICHCNX00 if present.
Installation data	Find occurrence anywhere in the installation data. You cannot use a filter for this field. The search is performed as a *substring scan*.

Table 81 describes the additional selection criteria types that can be specified. Enter / or S in the selection field for the criteria type. After you press enter, the panels to specify the criteria for each selected type are shown in sequence.

Table 81. Types of additional data set selection criteria - field descriptions

Field	Description
Profile fields	If this field is selected, you can specify additional selection criteria based on the contents of profile fields, except fields that relate to connects and segments. The selection panel is shown in "Additional selection - Profile fields" on page 136. If the field is not selected, the **Profile fields** selection criteria are not used but are saved for later use as long as you remain in **RA.D**.
Access list	If this field is selected, you can specify additional selection criteria based on the contents of the access list (ACL). The selection panel is shown in "Additional selection - Access list" on page 138. If the field is not selected, those selection criteria are not used but are saved for later use when you remain in **RA.D**.

Table 81. Types of additional data set selection criteria - field descriptions (continued)

Field	Description
Segment presence	If this field is selected, you can specify additional selection criteria based on the presence of application segments. When you select this option, segment selection and field selection panels open for specifying the criteria. If the output option **Show segments** has also been selected, the Segment presence selection criteria panel only shows the base segment of profiles that have the specific non-base segment. If **Segment presence** field is not selected, the selection criteria are not used but are saved for later use if you remain in **RA.D**.
Segment absence	If this field is selected, absence of a segment can be specified as an additional selection criterion. If the field is not selected, the selection criteria are not used, but are saved for later use if you remain in **RA.D**.

Table 82 describes the options for the report job and data formats. Enter / or S in the entry field to select an option.

Table 82. Data set report format and run options

Option	Description
Show segments	Select this option select the application segments that to be selected or excluded based on segment field values. If the field is not selected, the segment subset is not used but is saved in your ISPF profile for later use. This flag setting is saved in your ISPF profile.
All	Select this option with **Show segments** to show all segments for the selected profiles.
Enable full ACL	Select this option to gather the information necessary to add system-wide operations and default connects to universal groups to the access list. This option implies a full database read. If the **Print format** option is selected, the **Enable full ACL** format option only applies if **Print ACL** has also been selected or implied.
Specify scope	Select this option to limit the results to the scope of a user ID or group.
Print format	Select this option to format the data in print format instead of ISPF display format. This flag setting is saved in your ISPF profile and is shared by all RA options showing it. The options behind and below only apply if this one has been selected. See also “Print format” on page 145.
Customize title	If this field is selected together with **Print format**, you can change the subtitle for the selection. You can also add an extra title that is saved in your ISPF profile, including your company name, department, and phone number for example. This flag setting is saved in your ISPF profile and is shared by all RA options showing it.
Send as email	If this field is selected along with the **Print format** field, then a panel opens for specifying the email address destination for this report. The **Send as email** option only works if the SMTP options have been configured using the SETUP OUTPUT function. This flag setting is saved in your ISPF profile and is shared by all RA options showing it.

Table 82. Data set report format and run options (continued)

Option	Description
Background run	If this field is selected together with **Print format**, then a batch job is submitted to perform the query. This flag setting is saved in your ISPF profile and is shared by all RA options showing it.
Full detail form	If this field is selected together with **Print format**, then at a form-oriented subpage (one per profile) is used to include details. The subpages (profiles) are separated by horizontal dashed lines. The **Full detail form** setting implies the **Print ACL** and **Print names** settings. If the **Full detail form** field is not selected, each segment type is shown in its own tabular report. Sample results are shown in "Print format" on page 145. This flag setting is saved in your ISPF profile. If you have requested segments, they are shown on the same page with the other profile information.
Sort differently	If this field is selected together with **Print format**, then you can change the sort order using this option. This flag setting is saved in your ISPF profile. **Note:** If data is sent to an ISPF display panel, you can change the sort order from the panel by issuing the SORT primary command on the command line.
Narrow print	If this field is selected together with **Print format**, then the page width is limited to 79 characters, independent of the actual print file record length. If the field is not selected, then the page layout you specify must support a width of 132. However, the length can extend beyond that if the print file has a larger record length. This flag setting is saved in your ISPF profile and is shared by all panels that provide this option.

You can specify additional options for formatting and printing ACL data by selecting the options listed in Table 83. The settings for these options are saved in your ISPF profile.

Table 83. Format and print options for ACL data

Option	Description
Print ACL	If this field is selected along with the **Print format** field, then the access list is printed. The exact output format depends on the **Print names** and **Narrow print** settings. You can change the default sort order (by descending access) by selecting the **Sort differently** field. To print the access list in resolved form, use the **Resolve to users** field. If this field is not selected, the ACL information is not included in the results, greatly reducing the number of lines in the report. The **Print ACL** option is automatically implied if the **Full detail form** option is selected. By not printing the access list, the number of output lines can be greatly reduced.

Table 83. Format and print options for ACL data (continued)

Option	Description
Resolve to users	If this field is selected along with the **Print format** and **Print ACL** or **Full detail form**, then the access list is printed resolved to individual user IDs. This format takes into account the way RACF works with user and group permits and connect groups. The access list print can be further extended by selecting the **Incl operations** or **Print names** field.
Incl operations	The access list print includes access through the group-operations attribute if this field is selected along with any of the following fields **Print format** and **Print ACL** or **Full detail form** and **Resolve to users**. Depending on the setting for the **Enable full ACL** option, system-wide operations can also be included.
Print names	If this field is selected along with **Print format** and **Print ACL**, then the access lists are printed with names and installation data added. Only the first part of the installation data is printed, depending on the setting of option **Narrow print**. The **Print names** setting is implied if the **Full detail form** option is selected.

Additional selection - Profile fields

When the **Profile fields** option is selected, another selection criteria panel opens to specify additional selection criteria based on the profile list fields. This panel is shown in Figure 97.

```
  Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - RACF - Data set Selection
Command ===> ____________________________________________________________________
like SYS1.**
Specify additional selection criteria:
Profile properties
Creation date . . . __   ___________ (date: yyyy-mm-dd/ddMMMyyyy/TODAY-nnn)
On volume . . . . . ________     (disk/tape volser or filter)
Complex . . . . . ________     (complex name or filter)
Level . . . . . __   __      (installation defined resource level)

Enter "/" to specify inclusion criteria
/  Generic       /  Warning mode    /  Erase on scratch   /  Tape data set
/  Discrete      /  No warning      /  No erase           /  No tape data set

Enter "/" to limit       UACC or ID(*)       Success audit     No failure audit
_  Queued commands       __ _ 1. None        _ 1. Never        _ 1. Read
_  Userdata                   2. Execute        2. >=Read         2. <=Update
_  Universal access           3. Read           3. >=Update       3. <=Control
_  Unconditional ID(*)        4. Update         4. >=Control      4. <=Alter
                              5. Control        5. Alter          5. Ignore
                              6. Alter          6. Ignore
                              7. Ignore UACC
```

Figure 97. Additional data set profile selection - profile fields

In this example, an additional criterion has been added that only profiles with a UACC of READ or higher are to be shown.

The **Enter "/" to specify inclusion criteria** selection group contains option pairs that are selected by default. Based on the default settings, both generic and discrete profiles are to be shown in the report. If the **Enter "/" to limit** option is selected,

only those profiles with the characteristics specified are selected–generic and discrete profiles are not automatically included.

Table 84 describes the profile selection criteria supported for the Data set selection report.

Table 84. RACF Data set selection report - Profile selection criteria

Criteria	Description
Creation date operator	Use the following operators to select data based on the creation date. • < and <= for dates on or before the date specified. • > or >= for later dates. • = for exact dates • ¬= and <> for all but the specified date.
Creation date	The date the profile was defined. The date can be specified in any of the following formats: *ddmmmyyyy*, *01jan1998* for example. *yyyy-mm-dd*, *1998-01-01* for example. *TODAY* TODAY-*xx* where *xx* is a number of days. *DUMPDATE* or DUMPDATE-*xxx* (*DUMPDATE* is the database unload date)
On volume	Discrete profiles with a volume serial.
Complex	In a complex with this name, or a matching complex if a filter is used.
Level operator	Use the operator to determine a level present in the profile. Use < and <= for selection less than or equal to the level, > or >= for high level, = for exact level, ¬= and <> for all but the specified level.
Level	This numeric field indicates the data set level. This level is not set or updated by IBM utilities, but can be used by the installation.
Generic	Show generic profiles
Discrete	Show discrete profiles
Warning mode	Show profiles in warning mode
No warning	Show profiles not in warning mode
Erase on scratch	Show profiles with Erase
No erase	Show profiles without Erase
Tape data set	Show tape data set profiles
No tape data set	Show non-tape data set profiles.
Queued commands	Show only profiles that have one or more commands in the queue.
Userdata	Show only profiles with `userdata.`
Universal access	When this field is selected and Unconditional ID(*) is not, the UACC or ID(*) selection only applies to UACC. When both or neither are selected, the selection applies to UACC and ID(*).
Unconditional ID(*)	When this field is selected and Universal Access is not, the UACC or ID(*) selection only applies to ID(*). When both or neither are selected, the selection applies to UACC and ID(*).

Table 84. RACF Data set selection report - Profile selection criteria (continued)

Criteria	Description
UACC or ID(*)	Show all data set profiles with the specified UACC or an ACL entry with `ID(*)` that has the specified access level matching the operator value specified in the entry field.
Success audit	Show only profiles with this audit setting or higher.
No failure audit	Show only profiles with this audit setting or lower.

Additional selection - Access list

When the **Access list** option is selected, another selection criteria panel opens to specify additional selection criteria based on the access list fields. This panel is shown in Figure 98.

```
 Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                      zSecure Suite - RACF - Data set Selection
Command ===>
like SYS1.** with UACC or ID(*)>=READ
Specify additional selection criteria:
Find a combination of the following in the access list
# permits . . . . . __   ______              (operator: < <= > >= = <> ¬= )
# conditional permits __   ______            (operator: < <= > >= = <> ¬= )
Id on access list . ________                 (*, group or userid, or filter)
When resource . . . ____________________     (resource name or filter)
Access level  . . . __ _   1. None        When class  . . _  1. PROGRAM
                           2. Execute                       2. CONSOLE
                           3. Read                          3. APPCPORT
                           4. Update                        4. TERMINAL
                           5. Control                       5. JESINPUT
                           6. Alter                         6. SERVAUTH
                           7. Ignore                        7. Present
                                                            8. Ignore

Access list filtering
_   Only show matching ACL entries
```

Figure 98. Additional data set profile selection - access list

Table 85 describes the access list selection criteria supported for the Data set selection report.

Table 85. Data set selection report - Access List selection criteria

Criteria	Description
# permits	Match records based on the number of permits a profile has.
# conditional permits	Match records based on the number of conditional permits.
Id on access list	Match records that have the specified user or group ID value included on the access list. You can use the following filters in the ID specification: `%` for one character, `*` for one or more characters, and `:` for a substring scan. This value is not used for selection based on access that a user has through a group
When resource	You can select all data set profiles that have a conditional access list that includes the specified string in the resource name for the condition. You can use the following filters to specify this value: `%` for one character, `*` for one or more characters, and `:` for a substring scan.

Table 85. Data set selection report - Access List selection criteria (continued)

Criteria	Description
Access level Operator	Use the operator for selection based on the access level present in the ACL. • < and <= for less than or equal to the specified access level. • > or >= for higher access. • = for exact access. • ¬= and <> for all but the specified access level.
Access level	Show all data set profiles with at least one permit with an access level satisfying the Access level Operator.
When class	Show all data set profiles with a conditional access involving the class indicated.
Only show matching ACL entries	Show a subset of the access list, consisting of the access list entries that match all of the criteria selected on this panel.

Dataset profile tabular display

A sample data set profile display is shown in Figure 99.

Figure 99. Dataset profile display

The following fields of interest are shown.

Table 86. DATASET overview panel fields of interest

Field	Description
Profile key	The name of the data set profile. This value is a data set EGN mask.
Type	The profile type, one of GENERIC, VSAM, NONVSAM, MODEL, or TAPE.
UACC	Universal Access Level
Owner	Owning user or group. Together with QUAL, this value determines who can maintain the profile.
S	The lowest access level that results in auditing for successes.
F	The lowest access level that results in auditing for failures.
W	Profile is in Warning mode

You can view additional fields by scrolling to the right.

```

Table 87 describes the additional fields.

Table 87. DATASET overview panel - field descriptions

Field	Description
E	Erase-on-scratch flag
SgF	Global, or auditor setting for success and failure auditing.
iD(*)	Shows the access to this profile for `ID *`, which includes all RACF-defined users and groups, except for user IDs with the `RESTRICTED` attribute. This field only shows unconditional access.
Complex	Name for security data base
Notify	User to be notified of violation
Seclabel	Security label
RETPD	Retention period: days protection provided
CreateDat	Definition date
QUAL	Qualifier as modified by naming convention (`ICHCNX00` and `ICHCNV00`). This value together with `OWNER` determines who can maintain the profile.
Lv	The data set level. This level is not set or updated by IBM utilities, but can be used by the installation.
Pri	The relative audit priority for this profile.
InstData	Installation data. To modify this field it is easier to use the MI line command.

Dataset profile detail display

Select any profile on the data set profile table display to see the detail view. You can select entries by putting the cursor on the first character of a row selection field and pressing **Enter**, or by explicitly typing S and pressing **Enter**.

Figure 100. DATASET profile detail display

The fields described in Table 88 might be shown depending on the SETUP options and data availability.

Identification section

Table 88. Dataset Profile Detail panel - Identification section panel

Field	Description
Identification	To the far right, the complex name is shown.
Type	The profile type, one of GENERIC, VSAM, NONVSAM, MODEL, or TAPE.
Profile name	The key of the DATASET profile.
Volume serial list	Data set volume serials for discrete profiles.
Effective first qualifier	The first qualifier (user or group), as modified by the installation naming convention exit and table (ICHCNX00 and ICHNCV00), followed by the user name and the user or group installation data.
Owner	The owning user or group, followed by the user name and the user or group installation data.

Table 88. Dataset Profile Detail panel - Identification section panel (continued)

Field	Description
Installation data	Installation data field of the profile. If the installation data is too wide for the display, you can view and edit it more easily using the **MI** line command on the tabular display.

Access list fields. Table 89 describes these fields.

Table 89. Dataset Profile Detail panel - Access list fields

Field	Descriptions
User	User ID authorized through access list.
Access	Access level.
ACL id	ID on access list.
When	Conditional access applies (class / resource).
Name	Name of the user, if applicable.
InstData	Installation data of the user or group

The ACL data can be shown in several different formats. For example, the groups can be expanded to show the user IDs, duplicate references can be resolved, and operations access can also be shown. See "Access list display modes - reference material" on page 30 and "Managing the Access List display panel" on page 81 for information on these formats.

Safeguards fields. Table 90 describes these fields.

Table 90. DATASET Profile detail display - Safeguards fields

Field	Description
Erase on scratch	This flag shows whether data security erasure has been requested at the profile-level. Even for 'Yes', the option is only honored if SETROPTS ERASE has also been set.
Audit access success/failures	Two one-letter abbreviations for the access level that is to be audited for successes and failures (violations), respectively. This setting can be changed by the profile owner.
Global audit success/failures	Two one-letter abbreviations for the access level that is to be audited for successes and failures (violations), respectively. Only the auditor can change this setting.
User to notify of violation	Userid that has to receive a message when a violation occurs.
Days protection provided #	The RETPD of tape data sets, checked if the TAPEVOL class is active.

Other permissions fields. Table 91 describes these fields.

Table 91. DATASET Profile detail display - Other permissions fields

Allow all accesses WARNING	The value *Yes* indicates that warning mode is active. This mode implies that all accesses are permitted, but a warning message is indicated if the access normally results in a violation.

Table 91. DATASET Profile detail display - Other permissions fields (continued)

Universal access authority	The profile access level (UACC) that applies to all users, even users not defined in RACF. This access does not apply to users with the `RESTRICT` attribute.
Resource level	The data set level. This level is not set or updated by IBM utilities, but can be used by the installation.

Mandatory Access Control fields. Table 92 describes these fields.

Table 92. DATASET Profile detail display - Mandatory Access Control fields

Security label	Contains the resource security label used in Mandatory Access Control decisions (B1 security).
Security level	Contains the resource security level, which is the minimum level the user requires for reading the data set.
Categories list	Lists all security categories that the user requires for reading the data set.

Statistics fields. Table 93 describes these fields.

Table 93. DATASET Profile detail display - Statistics fields

Field	Description
Creating user's connect group	The then-current connect group of the user who created the data set profile.
Creation date	The date that the profile was created.

Additional, optional properties. Table 94 describes these fields.

Table 94. DATASET Profile detail display - Additional, optional property fields

Field	Description
Audit concern	A concatenation of audit concerns for the profile.
UsrNm	The names of the `userdata` fields, excluding those fields used by `CKGRACF`.
Flg	Flag associated with the `userdata` field
UserData	Contents of the `userdata` field
CKGRACF authority requirement	The authority required to change this DATASET profile by `CKGRACF` (SINGLE, DOUBLE or TRIPLE). That is, the number of administrators who must sanction a command.
Timed commands waiting for execution	Timed commands that have been approved and are now waiting for their execution date (*P*). Commands that have an end date scheduled, remain in this queue until their reversal date (*PR*).
Commands requiring administrator action	The commands that have not been fully authorized yet as per the value specified in **CKGRACF authority requirement** or per the system-wide default access level.
Inactive commands	Requested commands that were not fully authorized and then expired, were withdrawn, or were denied. These inactive commands are included in the audit trail with other commands that were not run.
Commands that have been executed	Commands that were fully authorized and run. These commands are included in the audit trail.

For an explanation of the CKGRACF data, see “RA.2 QUEUED - Queued commands” on page 185 and .

Line commands on a DATASET profile display

When you use the **/** line command to ask which line commands are permitted, the following table opens.

Table 95. Line commands on a DATASET profile display

Command	Meaning	Explanation
AC	Access Check for one user ID or group.	“RA.1 ACCESS - Access Check” on page 184
C	Copy data set profile.	“C - Copy” on page 55
D **DD**	Delete data set profile, or delete a non-base segment.	“D - Delete” on page 58
E	Display event logging.	“E - Event” on page 59
L	RACF `listdsd` command.	The results of the `listdsd` command are presented in a browse panel.
LD	RACF `listdsd DSNS` command.	Operates like the **L** command but also requests display of the data sets covered.
LR	List data sets covered by profile	“LR - List data sets covered via Report” on page 60
MI	Manage `instdata`.	“MI - Manage information” on page 61
MR	Manage `CKGRACF` authority requirements	“MR - CKGRACF mulitple authority requirement” on page 63
MU	Manage installation-defined USERDATA	“RA.3.9 USERDATA - User data management” on page 219
PE	Add or delete permit	“PE - Add or delete permit” on page 69
R **RR**	Recreate data set profile	“R - Recreate a profile” on page 70
S	Show additional information (same as just putting the cursor at the selection field)	“S - Select” on page 72
SE	Show application segments	“SE - Show application segments” on page 72 and “Application segments” on page 145.
X **XX**	Exclude a profile from `FORALL` processing.	“X - Exclude profile line command” on page 74
Z **ZZ**	Select profile for `FORALL` processing.	“Z - Select a profile” on page 74
34	Data Set List Utility	“34 - Data set list utility” on page 74

Add new DATASET profile or segment

You can add a new data set profile or empty segment to the current system with the **Add new DATASET profile or segment** option on the RACF Data set Selection panel (Figure 96 on page 132).

You can also add a new profile by copying an existing one. For details, see “C - Copy” on page 55. If you want to add a dataset profile or segment on another system, you must use a batch job.

Use the following procedure to add a new dataset profile or segment from the RACF Dataset Selection panel.

1. On the RACF Group Selection panel (Figure 86 on page 118), type a / or *S* in the **Add new DATASET profile or segment** field.
2. Press **Enter** to open the Data set Add panel.

```
 Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - RACF - Data set Add
 Command ===> ____________________________________________

 Dataset profile . . ____________________________________

 Owned by  . . . . . _______ (may also be set in the follow on update dialog)
 /   Define new DATASET profile

 _   Add DFP segment
 _   Add TME segment
```

Figure 101. Add DATASET profile panel

3. On the Add panel, you can add a new data set profile, add a segment to an existing data set profile, or add a combination of a data set and segment. For information on performing these tasks, see the ISPF panel help.
4. After specifying the field information, press **Enter** to the immediately add the data set or segment on the system where you are logged on.

   The RACF command response is only shown if there is a nonzero return code.

Notes:

1. When the Add panel displays, the default owner is provided to support users that do most of their additions in the same group. This value is stored in your ISPF profile based on previous add data set operations.
2. After the addition operation has successfully completed, a panel opens with the new profile or segments shown with modifiable fields for further customization. The format of this panel is the same as the detail display panel described in “Dataset profile detail display” on page 140.

Application segments

When the **Show segments** option has been selected, or the SE action command is used, application segments are shown.

The DATASET DFP segment shows the field **Resowner**, which is the resource owner (a user or group).

The DATASET TME segment detail display shows the Tivoli Management Environment role access specifications. The segment display shows the number of specifications and the first specification.

Print format

After you select the **Print format** option, a number of additional options are available for selection. The print data can be formatted in either tabular or form-oriented by selecting the **Full detail form** option. The tabular form sacrifices some detail in favor of a readable printout. The print format can either use a print

file width of at least 132 characters, or it can be limited to 79 columns through the **Narrow print** option. The prints can be sorted in another way than by profile name through the **Sort differently** option.

If **Sort differently** is selected, a sort order panel is displayed for each segment type to be shown. Figure 102 shows the sort order panel for the base segment.

```
  Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - RACF - Data set Sort Order
Command ===> ____________________________________________________________________
like SYS1.** with UACC or ID(*)>=READ
Specify up to 3 fields to act as
alternate base segment sort order
Select with 1 or / and optionally 2, 3
_ Profile name (default)
_ Qualifier (naming conventions)
_ Profile type
_ Installation data
_ Owner
_ Notify
_ Creation date (descending)
1 Universal access (descending)
_ Warning mode
_ Erase-on-scratch
_ Retention period (descending)
_ Level (descending)
_ By audit priority (descending)
```

Figure 102. Data set sort order panel

In the sort order panels, one can specify up to three sort keys by entering 1, 2, or 3 in front of the sort criteria. If you want to sort on just one column, it is also possible to use a / instead of 1.

Figure 103 shows an example of wide tabular print output of dataset profile base segments, sorted by descending universal access:

```

RA.R RESOURCE - General Resource profiles

The General Resource profiles panel provides access to simple profile selection functions. Use these functions to add a new profile or segment or select from profiles in a class like `FACILITY` or `GCICSTRN`.

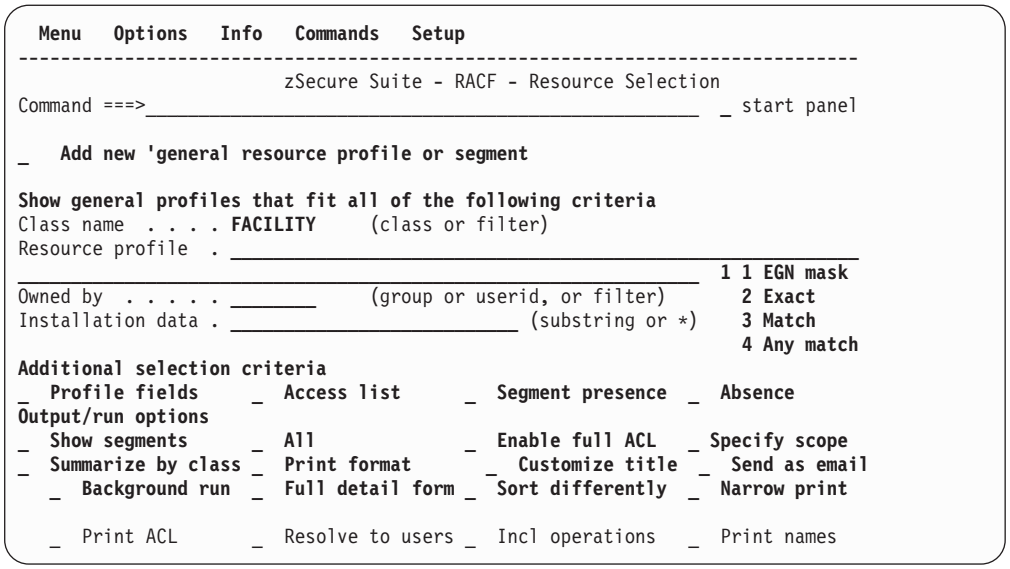

Figure 104. Simple resource profile selection

Table 96 describes the selection criteria on the RACF resource selection report panel.

Table 96. Resource selection - selection criteria

Class name	Limit the display of profiles to a CLASS defined in the CDT. For example, use JES* to show JESJOBS and JESSPOOL. If left blank, all resource classes are eligible.
Resource profile	If the EGN mask option is selected: an EGN filter to select resource set profiles can be used. If Exact is selected, the name of the resource profile must be specified.
EGN mask /Exact/Match /Any match	If the EGN mask is selected, the query interprets the profile name as an EGN filter (*- and %-characters are expanded). Exact selects the exact RACF profile. Match treats the profile field as a resource name and selects the best profile that could match the resource name. Any match treats the profile field as a resource name and selects all profiles that could match the resource name.
Owned by	Indicates the specified owner. The owner can be a user or group. You can use a filter specification in this field.
Installation data	Find occurrence anywhere in the installation data. A filter is not permitted. When this action runs, it performs a *substring scan*.

Additional selection criteria can be requested by entering / or *S* in the entry field for the following options.

Profile fields	For more selection criteria (except referring to connects and segments), use this checkbox. The selection panel is shown in "Additional selection - Profile fields" on page 156. If the field is not selected, the **Profile fields** selection criteria are not used but are saved for later use as long as you remain in **RA.R**.
Access list	For selection based on the contents of the access list (ACL). The selection panel is shown in "Additional selection - Access list" on page 158. If the field is not selected, those selection criteria are not used, but are saved for later use as long as you remain in **RA.R**.

Segment presence	If this field is selected, criteria can be specified for the presence of application segments. A segment selection panel and a segment field selection panel are shown. Only segments that contain data that is shown by the product are available. For example, the SSIGNON segment contains only the SSKEY field which is not shown because it is considered sensitive and is not supported for selection. unless the output option **Show segments** has also been selected, selecting the **Segment presence** option results in showing only the base segment of profiles that have the specific non-base segment.If the field is not selected, the selection criteria are not used but are saved for later use as long as you remain in **RA.R**.
Segment absence	If this field is selected, absence of a segment can be specified as an additional selection criterion. If the field is not selected, the selection criteria are not used but are saved for later use as long as you remain in **RA.R**.

Table 97 lists the output and run options you can specify.

Table 97. Resource selection - output and run options

Show segments	Show a selectable set of application segments for specifying select and exclude criteria based on segment field values. If this option is not selected, the segment subset is not used but is saved in your ISPF profile for later use. This flag setting is saved in your ISPF profile.
All	This option can be used with **Show segments** to show all segments for the selected profiles.
Enable full ACL	This checkbox can be used to gather the information necessary for adding system-wide operations and default connects to universal groups to the access list. It implies a full database read. If **Print format** is selected, it is only effective if **Print ACL** has also been selected or implied.
Specify scope	If this field is selected (with a /), you can limit the output to the scope of a userid or group.
Summarize by class	If this field is selected, the resource profiles are grouped by resource class. This flag setting is saved in your ISPF profile and is shared by all RA options showing it.
Print format	If this field is selected, output is in print format instead of ISPF display format. This flag setting is saved in your ISPF profile and is shared by all RA options showing it. The other print-related options are only available for selection if the **Print format** option is selected. See also “Print format” on page 170.
Customize title	If this field is selected together with **Print format**, you can change the subtitle for the selection as well as add an extra title that is saved in your ISPF profile, including your company name, department, and phone number for example. This flag setting is saved in your ISPF profile and is shared by all RA options showing it.
Send as email	If this option is selected along the **Print format** option, then a panel opens for specifying the email address destination for this report. The **Send as email** option only works if the SMTP options have been configured using the SETUP OUTPUT function. This flag setting is saved in your ISPF profile and is shared between all RA options showing it.

Table 97. Resource selection - output and run options (continued)

Background run	If this field is selected together with **Print format**, then a batch job is submitted to perform the query. This flag setting is saved in your ISPF profile and is shared by all `RA` options showing it.
Full detail form	If this field is selected together with **Print format**, forms (one subpage per group, separated by dashed lines) are used to include details. This selection implies selections for the **Print connects**, **Print names**, and **Print subgroups** options. This flag setting is saved in your ISPF profile. If you have requested segments, they are shown on the same page with the other group information. If the **Full detail form** field is not selected, each segment type is shown in its own tabular report. Sample output is shown in "Print format" on page 129.
Sort differently	If this field is selected together with **Print format**, then an alternate sort order can be selected. If you want to change the sort order in an ISPF display panel (**Print format** not selected), you can use the `SORT` primary command in the actual display. This flag setting is saved in your ISPF profile.
Narrow print	If this field is selected together with **Print format**, then the width of the page is limited to 79 characters, independent of the actual print file record length. If the field is not selected, then the page layout you specify must support a width of 132. However, the length can extend beyond that if the print file has a larger record length. This flag setting is saved in your ISPF profile and is shared by all panels showing this option.
Print ACL	If this option is selected along with the **Print format** option, then the Connects are printed. The exact output format depends on the **Print names** and **Narrow print** settings. The default sort order (by descending access) can be changed by selecting the **Sort differently** option. To print the access list in resolved form, use the **Resolve to users** option. This option is implied by **Full detail form**. By not printing the access list, the number of output lines can be greatly reduced. This flag setting is saved in your ISPF profile.
Resolve to users	If this option is selected along with the **Print format** and **Print ACL** or **Full detail form**, then the access list is printed resolved to individual user IDs, taking into account the way RACF works with user and group permits and connect groups. The access list information can be further extended by using the **Incl operations** and **Print names** options. This flag setting is saved in your ISPF profile.
Incl operations	If this field is selected along with **Print format** and **Print ACL** or **Full detail form** and **Resolve to users**, then the printed access list data includes access through the group-operations attribute. When `Enable full ACL` is selected, system-wide operations are also included. This flag setting is saved in your ISPF profile.
Print names	If this field is selected along with **Print format** and **Print ACL**, then the access lists are printed with names and installation data added. Only the first part of the installation data is printed, depending on the setting of option **Narrow print**. If **Narrow print** is selected, the revoke and resume dates for the Connect are not visible. This flag is implied by **Full detail form**. This flag setting is saved in your ISPF profile.

For more information about general resource reports, see the following topics:

- "Resource profile tabular display" on page 151

Resource profile tabular display

In the selection panel above, all profiles in the class FACILITY are being requested. This results in the following overview:

```
zSecure Admin General resource overview ------------------ Line 7 of 290

```

By scrolling to the right, additional fields can be displayed. The following fields of interest are shown:

Class	The profile class
Profile key	The profile name
T	The profile type: a *G* for a generic profile and blank otherwise.
UACC	The universal access level for the profile.
Owner	Owner
S	Audit success level
F	Audit failure level
W	Profile is in Warning mode
SgF	Global, or auditor setting for success and failure auditing.
ID(*)	This field shows the access to this profile for ID *. This access level applies to all RACF-defined users and groups, except for user IDs with the RESTRICTED attribute. This field only shows unconditional access.
Complex	Name for security data base
Notify	User to be notified of violation
Seclabel	Security label
CreateDat	Definition date
ApplData	Application data. The data listed depends on the profile class.
Lv	The resource level. This level is not set or updated by IBM utilities, but can be used by the installation.
Pri	The relative audit priority for this profile.
InstData	Installation data

Resource profile detail display

Select any profile on the resource profile table display to see the detail view. Selection can be done by putting the cursor on the first character of row selection field and pressing **Enter**, or by explicitly typing S there and pressing **Enter**.

A detail display is shown in Figure 105.

Figure 105. Resource profile detail display

The following fields of interest can be shown (depending on SETUP options, and data availability).

Identification section

Identification	To the far right, the complex name is shown.
Class	The profile class

Type	The profile type, one of GENERIC, VSAM, NONVSAM, MODEL, or TAPE. If this field is left blank, it indicates a DISCRETE profile.
Profile name	The key of the general resource profile. Long names are wrapped.
Volume serial list	Volume serials for discrete `TAPEVOL` profiles
Owner	The owning user or group, followed by the user name and the user or group installation data.
Installation data	Installation data field of the profile. If you need to edit wide data, it is easier to use the MI line command on the tabular display.
Application data	Application data. The meaning of this field depends on the class. If you need to edit wide data, it is easier to use the MI line command on the tabular display.

Access list section

User	Userid authorized through access list
Access	Access level
ACL id	Id on access list
When	Conditional access applies (class and resource name)
Name	Name of the user (if applicable)
InstData	Installation data of the user or group

Members section

The Members section lists the members of the resource profile. It is only shown if applicable.

Safeguards section

User to notify of violation	Userid that has to receive a message when a violation occurs.
Audit access success/failures	Two one-letter abbreviations for the access level that is to be audited for successes and failures (violations), respectively. This setting can be changed by the profile owner.
Global audit success/failures	Two one-letter abbreviations for the access level that is to be audited for successes and failures (violations), respectively. This is the setting that only an auditor can change.

Other permissions section

Allow all accesses WARNING	Shows *Yes* for warning mode. This implies all accesses are permitted but with warning messages where normally a violation would have occurred.
Universal access authority	The profile access level (UACC) that applies to all users, even those not defined in RACF. This access does not apply to users with the `RESTRICT` attribute.
Resource level	The resource level is not set or updated by IBM utilities, but can be used by the installation.

Mandatory Access Control section

Security label	This contains the resource security label used in Mandatory Access Control decisions (B1 security).
Security level	This contains the resource security level, which is the minimum access level the user must have to access the resource.
Categories list	This lists all security categories the user must have to access the resource.

Statistics section

Creation date	This is the date that the profile was created.

Additional, optional properties

Audit concern	A concatenation of audit concerns for the profile.
UsrNm	The names of the `userdata` fields, excluding those fields used by `CKGRACF`.
Flg	Flag associated with the `userdata` field.
UsrData	Contents of the `userdata` field.
CKGRACF authority requirement	The authority required to change this profile by `CKGRACF` (SINGLE, DOUBLE or TRIPLE). This authority level represents the number of administrators who must approve a command before it can be run.
Timed commands waiting for execution	Timed commands that have been approved and are now waiting for their execution date (*P*). Commands that have scheduled end date remain in this queue until their reversal date (*PR*).
Commands requiring administrator action	The commands that have not been fully authorized yet as per the **CKGRACF authority requirement authority** or per the system-wide default value.
Inactive commands	Requested commands that were not fully authorized and then expired, were withdrawn, or were denied. Inactive commands are included in the audit trail with other commands that were not run.
Commands that have been executed	Commands that were fully authorized and run. These commands are included in the audit trail.
Other CKGRACF data	The `userdata` fields used by `CKGRACF` for other purposes. An internal authority requirement can be shown here, typically for `CKGRACF` profiles. This is the authority setting associated with a `CKGRACF` command for which this profile determines the protection. It is not associated with the `CKGRACF` authority setting of this profile itself.

For an explanation of the `CKGRACF` data refer to "RA.2 QUEUED - Queued commands" on page 185 and "MR - CKGRACF mulitple authority requirement" on page 63.

The ACL can be shown in several different formats. For example, the ACL format shown is SORT– the groups can be expanded to the user IDs contained therein, duplicate references can be resolved, and operations access can also be shown. Refer to "Access list display modes - reference material" on page 30 and "Managing the Access List display panel" on page 81 for further explanation.

General Resource Class Overview

The query shown in "Resource profile detail display" on page 152 specifically selected the FACILITY class. If you do not select a specific class the profile overview is preceded by a class overview.

```

******************************* BOTTOM OF DATA ********************************
```

In this overview, the PROGRAM class has 45 discrete profiles. The SDSF class has 33 profiles, of which 18 are generic and 15 are discrete. The biggest general resource profile is in the PROGRAM class (2270 bytes), and the general resource class that uses the most space is FACILITY. The user, group, and data set profiles

are not listed in this overview. You can view the profiles by selecting any class in the overview. This selection opens the panel listing the profiles in the specified class.

Additional selection - Profile fields

If the *Profile fields* field is selected in the additional selection section, the panel shown in Figure 106 is displayed.

```

```

Figure 106. Advanced resource profile selection

In the example shown, we are looking for profiles in any CICS class that contain the substring *CEDA* in their member lists.

Table 98 describes the advanced selection criteria available for the RACF resource report.

Table 98. RACF resource selection - Advanced selection criteria

Criteria	Description
Creation date operator	Use the operator to determine the date for operator selection. Use < and <= for selection prior to or on the date specified, > or >= for later dates, = for exact dates, ^= and <> for all but the specified date.
Creation date	The date the profile was defined. The date can be specified in any of the following formats: • `ddmmmyyyy`, `01jan1998` for example. • `yyyy-mm-dd` , 1998-01-01 for example. • `TODAY` • `TODAY-xx` where *xx* is a number of days • `DUMPDATE` where *dumpdate* is the database unload date. • `DUMPDATE-xxx`
Complex	In a complex with this name, or a matching complex if a filter is used.
Profile	Text strings that can appear anywhere in the profile, `CEMT,DCMT` for example.
Memberlist	Text strings that can appear in the member list only, `CEMT,DCMT` for example.

Table 98. RACF resource selection - Advanced selection criteria (continued)

Criteria	Description
Level operator	Use the operator to determine a level present in the profile. Use < and <= for selection less than or equal to the level, > or >= for high level, = for exact level, ¬= and <> for all but the specified level.
Level	This numerical field indicates the resource level. This level is not set or updated by IBM utilities, but can be used by the installation.
Generic	Show generic profiles
Discrete	Show discrete profiles
Warning mode	Show profiles in warning mode
No warning	Show profiles not in warning mode
Queued cmds	Show only profiles that have one or more queued commands.
Userdata	Show only profiles with `userdata`
Universal access	When this field is selected and *`Uncond. ID(*)`* is not, the *`UACC or ID(*)`* selection only applies to UACC. When both or neither are selected, the selection applies to both UACC and ID(*).
Uncond. ID(*)	When this field is selected and *Universal access* is not, the *UACC or ID(*)* selection only applies to ID(*). When both or neither are selected, the selection applies to UACC and ID(*).
UACC or ID(*)	Show all general resource profiles with the specified UACC or an ACL entry with `ID(*)` that has the specified access level for the Operator specified in the entry field.
Show merged memberlist	Specify **1** for 'normal' output. Specify **2** to show a member overview first, followed by a profile overview at a deeper level. Specify **3** to show an overview of duplicate members, followed by a profile overview at a deeper level.

The merged `memberlist` option is not the way to find all profiles with members that cover a given resource. Use option **RA.3.7 Match** (see "RA.3.7 MATCH - Find profiles that cover a data set or resource" on page 216) instead.

A sample profile display is the following figure.

```

Access list filtering
_   Only show matching ACL entries
```

Figure 107. Access list selection

Table 99 describes the supported selection criteria.

Table 99. Resource selection report - selection criteria

Criteria	Description
# permits	Specify the number of permits the profile should have.
# conditional permits	Specify the number of conditional permits the profile should have.
Id on access list	User or group on the access list (access that a user has through a group is *not* supported in this selection). You can use filters, consisting of % (one char), * (>1 char) and : (search).
When resource	You can select all resource profiles that have a conditional access list involving the string specified in the resource name for the condition. You can use the following filters in the ID specification: % for one character, * for one or more characters, and : for a substring scan.
Access level Operator	Use the operator to determine an access level present in the ACL. Use < and <= for selection less than or equal to the level, > or >= for high access, = for exact access, ¬= and <> for all but the specified access level.
Access level	Show all resource profiles with at least one permit with an access level satisfying the Access level Operator.
When class	Show all resource profiles with a conditional access involving the class indicated.
Only show matching ACL entries	Show a subset of the access list, consisting of the access list entries that match all of the criteria selected on this panel.

Line commands on a RESOURCE profile display

When you use **/** line command to ask which line commands are permitted, the following table is shown.

Table 100. Line commands on a RESOURCE profile display

Command	Meaning	Explanation
AC	Access Check for one `userid` or group	"RA.1 ACCESS - Access Check" on page 184
C	Copy general resource profile	"C - Copy" on page 55
CC	Copy to a different class	"CC - Copy to a different class" on page 56
D **DD**	Delete general resource profile, or delete a non-base segment,	"D - Delete" on page 58
E	Display event logging	"Reporting on general resource events (EV.R)" on page 567
K	Set or delete APPCLU session key	"K - Manage APPCLU and PTKDATA keys" on page 59
L	RACF `rlist` command	The output from the `rlist` command is presented in a browse panel.
MI	Manage information	"MI - Manage information" on page 61
MR	Manage CKGRACF authority requirements	"MR - CKGRACF mulitple authority requirement" on page 63
MU	Manage installation-defined USERDATA	"RA.3.9 USERDATA - User data management" on page 219
PE	Add or delete permit	"PE - Add or delete permit" on page 69
R **RR**	Recreate general resource profile	"R - Recreate a profile" on page 70
S	Show additional information	"S - Select" on page 72
SE	Show application segments	"SE - Show application segments" on page 72 and "Application segments" on page 161.
X **XX**	Exclude a profile from `FORALL` processing.	"X - Exclude profile line command" on page 74
Z **ZZ**	Select profile for `FORALL` processing.	"Z - Select a profile" on page 74

Add new general resource profile or segment

By pressing the push button *Add new general resource profile or segment* on the RA.R panel (put the cursor on it and press ENTER or put a / in front of it and press ENTER), you can request addition of a new, vanilla, general resource profile, or addition of an empty segment on the current system only. If you want to make a copy of an existing profile instead of building from scratch, or add a profile on another system through a batch job, type the profile name in the simple selection panel, display it, and then put the C (Copy) line command in front of it, instead of using this push button. The simple selection panel is described in "RA.R RESOURCE - General Resource profiles" on page 147.

When you press the *Add new general resource profile* or *segment* button the panel shown in Figure 108 on page 161 is displayed.

```
 Menu   Options   Info   Commands   Setup

_   Add EIM segment                  _  Add STDATA segment
_   Add ICSF segment                 _  Add SVFMR segment
_   Add ICTX segment                 _  Add TME segment
_   Add KERB segment

Seclevel  . . . . .
Custom field type .    1. CHAR  2. NUM  3. FLAG  4. HEX
```

Figure 108. Add resource profile panel

When a new general resource profile is added, you specify a resource profile owner. The owner of the resource profile is saved to your ISPF profile and becomes the default profile owner for new profiles that you add. You can choose one of the following options: add a new profile, add a new segment to an existing profile, or add a new profile with a new segment. For the CFDEF segment, you are prompted to specify the Custom field type. For the SECLABEL class, you are prompted to specify the **Seclevel**. For the DIGTRING class, a panel displays which allows you to specify the Key ring name and Key ring owner. After you press Enter, the add command runs immediately on the system you are logged on to. The RACF command response is only shown if there is a nonzero return code. Next, the new profile, or segments are displayed with modifiable fields for further customization. The format of the display is the same as the detail display described in "Resource profile detail display" on page 152.

Application segments

When the *Show segments* option is selected, or the SE action command is used, application segments are displayed.

- "CDTINFO segment (CDT class)" on page 162
- "CFDEF segment (CFIELD class)" on page 163
- "CERTDATA segment (DIGTCERT class)" on page 164
- "DLFDATA segment (DLFCLASS class)" on page 165
- "EIM segment (LDAPBIND and FACILITY class)" on page 165
- "ICSF segment (CSFKEYS, GCSFKEYS, XCSFKEY,and GXCSFKEY class)" on page 166
- "ICTX segment" on page 166
- "IDIDMAP Identity propagation mapping" on page 167
- "PROXY segment (LDAPBIND and FACILITY class)" on page 167
- "SESSION segment (APPCLU class)" on page 168
- "SSIGNON segment (PTKTDATA class)" on page 168
- "SIGVER segment (General Resource class)" on page 168
- "STDATA segment" on page 169

- "SVFMR segment (SYSMVIEW class)" on page 169
- "TME segment" on page 170
- "DIGTNMAP Certificate Filters" on page 170

CDTINFO segment (CDT class)

The CDTINFO segment for the CDT class is not supported under z/VM. In a RACF database that is shared between z/VM and z/OS, process these segments from the zSecure for z/OS product.

The CDTINFO segment is only valid for the CDT resource class. It is used to define classes in the dynamic CDT.

In this segment, the POSITs of related grouping and member classes are kept synchronized. When you overtype the POSIT of a grouping or member class with a value, an additional command is generated to also change the POSIT of the related class to the same value. You can still have grouping and member class pairs with unlike POSITs by setting the POSITs before creating the grouping and member relation.

Table 101. CDTINFO segment (CDT class)

Overview field	Detail field	Explanation
Pos	**POSIT (options set id)**	The options set id, a number in the range 0 to 1023 identifying a set of SETROPTS options that govern the activity of the user-defined class and all other classes having the same POSIT value.
Grouping	**Related grouping class**	For member classes, this field contains the name of the related grouping class
Members	**Related member class**	For grouping classes, this field contains the name of the related member class
RC	**Default not-found RC**	The default return code for the user-defined class
Oper	**OPERATIONS honored**	Whether OPERATIONS authority is honored for the user-defined class
UACC	**Default UACC**	The default universal access for the user-defined class.
Max	**Maximum length**	The maximum length of resource and profile names of the user-defined class.
MxE	**Maximum length with ENTITY**	The backward compatible maximum profile name length to be used with the ENTITY keyword form of the RACROUTE macro.
Scl	**SECLABELs required**	Whether SECLABELs are required for profiles in the user-defined class.
MAC	**MAC checking**	Which type of mandatory access control (MAC) processing is required for the user-defined class.
PrA	**Profile definition allowed**	Whether profiles are permitted in the user-defined class
GnA	**GENERIC/GENCMD status**	Whether SETROPTS GENERIC and GENCMD are permitted for the class

Table 101. CDTINFO segment (CDT class) (continued)

Overview field	Detail field	Explanation
Racl	**RACLIST status**	Whether profiles in the user-defined class can or cannot be SETROPTS RACLISTed, or are required to be RACLISTed.
Genl	**GENLIST status**	Whether the user-defined class can be GENLISTed
Sig	**Send ENF signal**	Whether an ENF signal must be sent when the user-defined class is being RACLISTed, NORACLISTed, or RACLIST REFRESHed.
Qu	**Generic scan limit (quals)**	The number of qualifiers at the start of the profile name that cannot be generic.
Lwr	**Profile names case sensitive**	Whether profile names in the user-defined class are kept as is or are converted to uppercase.
AN#S	**Syntax 1st character (raw)**	The syntax rules for the first character of a profile name in the user-defined class.
AN#S	**Syntax remainder (raw)**	The syntax rules for the remainder characters of a profile name in the user-defined class.

CFDEF segment (CFIELD class)

CFDEF segments can only be added at **CFIELD** profile creation time, and not later. When adding a **CFIELD** profile, a **CFDEF** segment and a Custom field data type are required.

Table 102. CFDEF segment (CFIELD class)

Overview field	Detail field	Explanation
RACF header	**Custom field listing header**	The heading to display in the output for the `LISTUSER` or `LISTGRP` command whenever the **CSDATA** segment is listed.
Type	**Custom field type**	The data type of the custom field. Valid data types are **CHAR**, **NUM**, **FLAG**, and **HEX**.
MaxL	**Custom field max length**	Maximum length of the value supported in `NUM`-type custom fields.
MinVal	**Custom field min value**	Minimum value supported in `NUM`-type custom fields.
MaxVal	**Custom field max value**	Maximum value supported in `NUM`-type custom fields.
CF1	**Custom field first char**	Syntax value of first character of `CHAR`-type fields. The default format prints a string such as `AN#S` where the letters indicate which character is permitted for a first character in `CHAR`-type fields. Possible values are: **A** for alphabetic **N** for nationals **#** for numerics **S** for all other characters

Table 102. CFDEF segment (CFIELD class) (continued)

Overview field	Detail field	Explanation
CF0	**Custom field other chars**	Syntax value of non-first characters of CHAR-type fields. The default format prints a string such as AN#S where the letters indicate which character is permitted for non-first characters in CHAR-type fields. Possible values are: **A** for alphabetic **N** for nationals **#** for numerics **S** for all other characters
Mix	**Custom field mixed chars**	Indicates whether mixed case characters are permitted in CHAR-type custom fields.
Help text	**Custom field help text**	Provides the help text for the custom field.

CERTDATA segment (DIGTCERT class)

The DIGTCERT CERTDATA segment contains digital certificate information.

Table 103. CERTDATA segment (DIGTCERT class)

Overview field	Detail field	Explanation
Profile key	**Ring profile name**	Profile key
#Cert	n/a	Number of certificates
Digital certificate labels	**Digital certificate labels**	Label of the certificate
User	**User**	Userid associated with the certificate
Tru	**Tru**	Whether the certificate is marked as trusted
Cert. sta	**Certificate startdate**	Certificate is valid from this date/time
Cert. end	**Certificate enddate**	Certificate is valid until this date/time
Subject's distinguished name	**Subject's distinguished name**	The user for whom the certificate was issued
Issuer's distinguished name	**Issuer's distinguished name**	Name of the issuer of the certificate
Serial number	**Serial number**	Serial number of the certificate
Key Type	**Private Key Type**	Type of private key
n/a	**Private Key Size**	Contains the size, in bits, of the private key
n/a	**Certificate lser**	Contains the last eight bytes of the last certificate that was signed with this key
n/a	**Certificate AltName email**	The email addresses of the subject as found in the subjectAltName extension of the certificate.
n/a	**Certificate AltName domain**	The domain names of the subject as found in the subjectAltName extension of the certificate.
n/a	**Certificate AltName IP addr**	The IP addresses of the subject as found in the subjectAltName extension of the certificate.
n/a	**Certificate AltName URI**	The universal resource identifiers of the subject as found in the subjectAltName extension of the certificate.

Table 103. CERTDATA segment (DIGTCERT class) (continued)

Overview field	Detail field	Explanation
n/a	**RACF format**	The keyUsage extension of the certificate as RACF would show it.
n/a	**X509 format**	The keyUsage extension of the certificate as defined by the X.509 standard.
n/a	**Ringname**	A list of full names (userid and keyringname) of the keyrings to which this digital certificate is connected.

CERTDATA segment (DIGTRING class)

The DIGTRING CERTDATA segment contains key ring information.

Table 104. CERTDATA segment (DIGTRING class)

Overview field	Detail field	Explanation
n/a	**Certificate Label**	The certificate label
n/a	**Usage**	The type of authorization the certificate is used for within the ring
n/a	**Dflt**	Indicator whether the certificate is the default certificate within the ring
n/a	**Certificate name**	The certificate name

DLFDATA segment (DLFCLASS class)

The DLFDATA segment is only valid for the DLFCLASS resource class. It specifies information that controls DLF objects in profiles in the DLFCLASS.

Table 105. DLFDATA segment (DLFCLASS class)

Overview field	Detail field	Explanation
Ret	**Retain flag byte**	Retain flag byte
Jobs	**Jobnames**	The number of job names on the overview , and job names on the detail level.

EIM segment (LDAPBIND and FACILITY class)

The EIM segment is used to store Enterprise Identity Manager information. The EIM segment is only valid for user IDs and the LDAPBIND and FACILITY resource classes. The three Registry fields are only valid on the IRR.PROXY.DEFAULTS profile in the FACILITY class.

Table 106. EIM segment (LDAPBIND and FACILITY class)

Overview field	Detail field	Explanation
EIM DomainDN	**EIM Domain Distinguished Name**	The distinguished name of the EIM domain.
Options	**EIM options**	Options that control the EIM configuration.
Local Registry	**Local RACF registry for EIM**	Name of the local RACF registry in EIM domains.
Kerberos Registry	**Kerberos registry for EIM**	Name of the Kerberos registry in the EIM domain that the system uses.
X509 Registry	**X509 registry for EIM**	Name of the X509 registry in the EIM domain that the system uses.

ICSF segment (CSFKEYS, GCSFKEYS, XCSFKEY,and GXCSFKEY class)

The ICSF segment is used to store Integrated Cryptographic Service Facility attributes for the keys that are controlled by general resources profiles in classes CSFKEYS, GCSFKEYS, XCSFKEY, and GXCSFKEY.

Table 107. ICSF segment

Overview field	Detail field	Explanation
ASE	**Asym. key usage SECUREEXPORT**	This field specifies whether the asymmetric key controlled by general resources profiles in the ICSF related classes can be used to export or import symmetric keys.
AHS	**Asym. key usage HANDSHAKE**	This field specifies whether the asymmetric key controlled by general resources profiles in the ICSF related classes can be used to protect communication channels.
SKEx	**Symmetric key exportable by**	This field indicates whether the symmetric keys covered by general resources profiles in the ICSF related classes are permitted to be exported.
SCW	**Symmetric Key CPACF wrap**	This field indicates whether the symmetric keys covered by general resource profiles in the ICSF related classes are allowed to be rewrapped. **Note:** The key rewrapping operation requires the key to exist in plain text outside of the tamper-resistant hardware. If your site requires that a particular encrypted key never exists in plain text outside of *tamper-retamper-resistant*, then SYMCPACFWRAP=NO.
PKDSlbl	**PKDS labels**	This repeated group field specifies a list of the ICSF key labels pertaining to public keys which can be used to export the symmetric keys covered by general resources profiles in the ICSF related classes.
Klbl#	**# PKDS labels**	Count of PKDS labels.
Clbl	**Certificate labels**	This repeated group field specifies a list of digital certificate labels that can be used to export the symmetric keys controlled by general resources profiles in the ICSF related classes.
Clbl#	**# Certificate labels**	Count of certificate labels.

ICTX segment

The ICTX segment contains the configuration options that control the Identity Context Extension (ICTX). It is only valid for specific profiles in the LDAPBIND class.

Table 108. ICTX segment (LDAPBIND class)

Overview field	Detail field	Explanation
EIM	**ICTX uses EIM to map**	The ICTX identity cache uses Enterprise Identity Mapping (EIM) services to find a mapping to a z/OS user ID

Table 108. ICTX segment (LDAPBIND class) (continued)

Overview field	Detail field	Explanation
Use	**ICTX stores mapping**	The ICTX identity cache stores an identity mapping to a local z/OS user ID when provided by the application
Req	**ICTX requires mapping**	The ICTX identity cache requires identity mapping to a z/OS user ID
Time	**ICTX mapping timeout**	The time (in seconds) the ICTX identity cache stores an identity mapping

IDIDMAP Identity propagation mapping

The IDIDMAP display contains identity propagation mapping information.

Table 109. Identity propagation mapping - segment field descriptions

Overview field	Detail field	Explanation
#Maps	n/a	Number of identity mappings in the profile.
Profile key	**Profile name**	The profile name.
n/a	**Mapping label**	The labels for the identity mappings.
n/a	**Userid**	The userids to which the distributed identities are mapped.
n/a	**Registry**	The registries for the distributed identities mapped.

KERB segment (REALM class)

The KERB segment is only valid for the REALM resource class. It specifies z/OS SecureWay Server Network Authentication and Privacy Service information.

Table 110. KERB segment (REALM class) - Segment field descriptions

Overview field	Detail field	Explanation
Kerberos name	**Kerberos name**	Kerberos realm name.
MinTktLife	**Minimum ticket life**	Minimum ticket life granted for this realm in seconds.
DefTktLife	**Default ticket life**	Default ticket life granted for this realm in seconds.
MaxTktLife	**Maximum ticket life**	Maximum ticket life granted for this realm in seconds.
Encryption	**Supported encryption types**	Types of encryption that can be used for this realm.
Chk	**Validate address in tickets**	This field specifies whether the Kerberos server validates network addresses in encrypted tickets as part of ticket validation processing.

PROXY segment (LDAPBIND and FACILITY class)

The PROXY segment is only valid for the LDAPBIND and FACILITY classes. It is used to store LDAP proxy server information.

Table 111. PROXY segment (LDAPBIND and FACILITY class) - Segment field descriptions

Overview field	Detail field	Explanation
LDAP host	**LDAP host**	Host of LDAP server to contact

Table 111. PROXY segment (LDAPBIND and FACILITY class) - Segment field descriptions (continued)

Overview field	Detail field	Explanation
Bind name	**Bind distinguished name**	Bind information for LDAP server being contacted

SESSION segment (APPCLU class)

The SESSION segment is only valid for the APPCLU resource class. This segment is used to control the establishment of sessions between logical units under LU6.2.

In the detail view of the segment, the session entity names are listed, the numbers of failures, and the session key (if the input is not an UNLOAD).

No information is shown from the SSIGNON segment (classes PTKTDATA and KEYSMSTR) because this segment only contains an encryption key.

Table 112. SESSION segment (APPCLU class)

Overview field	Detail field	Explanation
ConvSecL	**Conversation security flags**	Conversation security flags
Loc	Lockout flag	Session flag byte
LastKeyChg	**Session key last change date**	Session key last change date
KyInt	**Session key days to expiry #**	Session key days to expiration
KyTry	**Invalid attempts #**	Invalid attempts
KyMax	**Failed tries before lockout #**	Invalid attempts before lockout
#Sent	n/a	Number of session entities
n/a	**Session key (clear text)**	Session key in clear text
n/a	**Hexadecimal session key**	Session key in hexadecimal

SSIGNON segment (PTKTDATA class)

The `SSIGNON` segment is only valid for the `PTKTDATA` class. It is used to store secured signon keys. Table 113 lists the fields available for this segment.

Table 113. SSIGNON segment (PTKDATA class)

Overview field	Detail field	Explanation
SIGVER	**SIGVER segment**	Indicates the start of the segment
SIGREQD	**Signature required**	Indicates whether the module must have a signature. Value can be `YES` or `NO`.

SIGVER segment (General Resource class)

The `SIGVER` segment is only valid for the General Resource class. This segment provides information about when a signature verification occurred and whether a load was failed because signature verification failed.

Table 114. SIGVER segment (General Resource class)

Overview field	Detail field	Explanation
SIGVER	**SIGVER segment**	Indicates the start of the segment
SIGREQD	**Signature required**	Indicates whether the module must have a signature. Value can be `YES` or `NO`.
FAILLOAD	**Loader SIGVER response**	The following values can be displayed. • ANYBAD • BADSIGONLY • Never
SIGAUDIT	**Signature auditing condition**	The value in this field indicates the conditions under which RACF records an SMF type 80 record with qualifier code 86. The following conditions are possible. • Bad signature • Any failing signature • Success • All • None

STDATA segment

The `STDATA` segment is only valid for the STARTED resource class. It is used to control security for started tasks.

Table 115. STDATA segment (STARTED class)

Overview field	Detail field	Explanation
Proc.Jobname	**Profile name**	Procedure/jobname combination
Userid	**Started task RACF userid**	RACF `userid` to be used for started procedure
Group	**Started task RACF group**	RACF group to be used for started procedure
Trus	**Trusted - allow any, log all**	Trusted - all is authorized and logged
Priv	**Privileged - allow any, nolog**	Privileged - all is authorized, do not log
Trac	**Trace - issue IRR812I**	Trace

SVFMR segment (SYSMVIEW class)

The `SVFMR` segment is only valid for the `SYSMVIEW` resource class. This segment defines profiles associated with a particular SystemView® for MVS application.

Table 116. SVFMR segment (SYSMVIEW class)

Overview field	Detail field	Explanation
SV script	**Default logon scripts**	Systemview default logon script
SV parms	**SVFMR parameter list**	Systemview parameter list

TME segment

The TME segment specifies that information in the Tivoli Security Management Application is to be added, changed, or deleted. TME role access specifications can be present for all resource classes, the other fields can only be present for the ROLE class.

Table 117. TME segment

Overview field	Detail field	Explanation
Roles	**TME role access specifications**	TME role access specifications (count on overview)
TME parent role	**TME parent role**	TME parent role
Child (count on overview)	**TME child roles**	TME child roles
Grps (count on overview)	**TME grps**	Groups referring to this ROLE
Rsrcs	**TME resource access specifications**	TME resource access specifications

DIGTNMAP Certificate Filters

The `DIGTNMAP BASE` segment contains Certificate Filters information.

Table 118. DIGTNMAP Certificate Filters

Overview field	Detail field	Explanation
n/a	**Certificate filter label**	List of labels describing the digital certificate filters that map to the key of this profile.
n/a	**Target ID of certificate fltr**	RACF `userid` that the digital certificate filters described in this profile map to
n/a	**Certificate filter is trusted**	The trusted status of the digital certificate filters that map to the key of this profile.
Certificate filter name	**Certificate filter name**	Issuer and subject name separated by ¢

Print format

Behind the *Print format* checkbox, a number of additional options can be chosen. The options behind and below only apply if this one has been selected. The print format is either tabular or form-oriented and can be selected by the *Full detail form* checkbox. The tabular form sacrifices some detail in favor of a readable printout. The print format can either use a print file width of at least 132, or forced into 79 columns through the *Narrow print* checkbox. The prints can be sorted in another way than by profile name through the *Sort differently* checkbox.

If *Sort differently* is selected, a sort order panel opens for each segment type to be included in the output data. If you specify both *Print ACL* and *Print names*, you can specify access list sort order on the right half of the base segment sort order panel. For example, for the base segment:

```
  Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - RACF - Resource Sort Order
Command ===>
All profiles
Specify up to 3 fields to act as          Select one field to act as
alternate base segment sort order         access list sort order
Select with 1 or / and optionally 2, 3    Select with 1 or /
_ Profile name (default)                  _ Decreasing access
_ Member class                            _ Userid
_ Profile type                            _ Id in access list
_ Installation data
_ Owner
_ Notify
1 Creation date (descending)
_ Universal access (descending)
_ Warning mode
_ Application data
_ Retention period (descending)
_ Level (descending)
_ By audit priority (descending)
```

In the sort order panels, one can specify up to three sort keys by entering *1*, *2*, or *3*in front of the sort criteria. If you want to sort on just one column, it is also possible to use a / instead of 1.

The following figure shows an example of wide tabular print output of general resource profile base segments, sorted by descending creation date:

```
RACF class FACILITY  - complex DINO     19Sep2000  18:34                                                                    page    1
Class FACILITY with owner SYSAUTH, sorted by creation

Profile key                              TW UACC    Owner    S/F SgF Created Notify  Lv Pri InstData
IRR.RADMIN.LISTUSER                         NONE    SYSAUTH    R     16Sep00          0
IRR.RADMIN.*                             G  NONE    SYSAUTH    R     16Sep00          0
$C2R.OPTION.RA.H                            READ    SYSAUTH    R     12Sep00          0
$C2R.OPTION.RA.H.3                          READ    SYSAUTH    R     12Sep00          0
$C2R.OPTION.CH.**                        G  NONE    SYSAUTH    R     25Aug00          0
$CNG.SCP.G.SYSAUTH.SYSPROG                  NONE    SYSAUTH          10Jun00          0
BPX.DEFAULT.USER                            NONE    SYSAUTH  R R      8Mar00          0    UNIX DEFAULT.USER MUST BE DISCRETE
     Appldata: C#UNIXU/C#UNIXG
IRR.DIGTCERT.ADD                            NONE    SYSAUTH  R R      3Mar00          0    ABILITY TO ADD A CERTIFICATE
```

The TW columns indicate Type and Warning status, respectively. For the meaning of the other columns see “Resource profile tabular display” on page 151. The classes always start on a new page.

When *Narrow print* is checked, the output is almost the same, except that installation data (if any) is on a separate line. This changes if *Print ACL* is also selected, the output is shown with each access level on a separate line:

```
RACF class FACILITY  Complex DINO     19Sep2000  18:38             page    1
Class FACILITY with owner SYSAUTH, sorted by creation

RA.S SETTINGS - SETROPTS and class settings

Menu option **RA.S** produces two reports, respectively showing the SETROPTS settings and class information from both the SETROPTS settings and the class descriptor table (CDT). They are designed to be a convenient way to change SETROPTS settings and class attributes.

```
zSecure Display Selection                          1 s elapsed, 0.6 s CPU
Command ===> ____________________________________________________ Scroll===> CSR
  Name     Summary Records Title
_ SETROPTS       1       1 RACF SETROPTS system settings
_ RACFCLAS     195     195 RACF class settings
****************************** Bottom of Data ********************************
```

The SETROPTS detail display is identical to “SETROPTS - RACF settings report” on page 266.

Class settings tabular display

The class settings display looks like this:

```
RACF class settings                                              Line 1 of 195
Command ===> ____________________________________________________ Scroll===> CSR
                                                  25 Apr 2005 00:07
   Class    Active Description
__ ACCTNUM  Active TSO account numbers__ ACICSPCT Active CICS program control table

__ APPCLU   Active Verify ID of partner logical units during VTAM session estab
__ APPCPORT Active Controls which user IDs can access the system from a given L
__ APPCSERV Active Controls whether a program being run by user can act as a se
__ APPCSI   ______ Controls access to APPC side information files
__ APPCTP   ______ Controls the use of APPC transaction programs
__ APPL     Active Controls access to applications
```

By scrolling to the right, additional fields can be displayed. The following fields of interest are shown:

Class
Name of the class in the class descriptor table (CDT).

Active
RACF protection for this class is active (due to a SETROPTS CLASSACT command).

Description
A short explanation of the purpose of the class.

Generic
Generic profile checking for this class is active (due to a SETROPTS GENERIC command). This implies that generic command processing for this class is active.

GenCmd
Generic profile command processing for this class is active due to a SETROPTS GENCMD or a SETROPTS GENERIC command.

Audit
Command auditing for this class is active due to a `SETROPTS AUDIT` command.

Logopt
Auditing options for this class, due to a SETROPTS LOGOPTIONS command. The LOGOPT values can be *Always*, *Failure*, *Never*, *Profile* (determined by the logging options of the profile), and *Success*.

Global
Global Access Checking activity. This value is *Undefined* if Global Access checking is not permitted. It is *set* if Global Access checking is active, and *not set* if Global Access checking is inactive.

Raclist
This class has been RACLISTed which means that both generic and discrete profiles for this class are loaded into storage that is shared between address spaces. This processing occurs as a result of a `SETROPTS RACLIST(`*class*`)` command.

Genlist
This class has been GENLISTed as a result of a SETROPTS GENLIST command. A `GENLIST`ed class specifies that all generic profiles for the class are retained in-storage that is shared between address spaces.

Stats
Statistics are collected for this class (due to a SETROPTS STATISTICS command).

Complex
The name of the complex examined.

System
The name of the system examined.

RC
The default return code for this class. This code is returned when no matching profile can be found at a RACHECK. The result codes and their meanings are *0* (Grant access), *4* (Indeterminate: depends on resource manager) and *8* (Fail access).

Oper
This column contains the text OPER if the OPERATIONS attribute applies to this class. This means that all users with this attribute have access unless access is specifically denied.

Pos
This field contains the options set id, a number in the range *0* to *1023* identifying a set of SETROPTS options that govern the activity of this class and all other classes having the same POSIT value. Whenever a SETROPTS command is issued for any class with a specific POSIT value, it applies to all classes with that same POSIT.

Grouping
For member classes, this field contains the name of the related grouping class.

Members
For grouping classes, this field contains the name of the related member class.

Where
This field indicates profile residency. The possible WHERE values and their meanings are:

Genlist
Indicates profiles that have been GENLISTed as a result of a SETROPTS GENLIST command, which means that all generic profiles are retained in-storage shared between address spaces, but discrete profiles are not resident.

NoGenl
SETROPTS GENLIST is not permitted for this class. SETROPTS RACLIST is permitted but has not been specified.

NoList
SETROPTS RACLIST and SETROPTS GENLIST are not permitted for this class, usually because the applications automatically issue the RACLIST command.

NoRacl
SETROPTS RACLIST is not permitted for this class; SETROPTS GENLIST is, but has not been specified.

Nowhere
Profiles not permitted in this class.

RaclGbO
The profiles are resident only because they have been RACLISTed by an application via a RACROUTE macro with GLOBAL=YES specified.

Raclist
Profiles have been RACLISTed as a result of a SETROPTS RACLIST command, which means that they reside in a data space or in (E)CSA.

RaclReq
Profiles must reside in-storage if class is active.

(blank)
Class has not been RACLISTed or GENLISTed, but it would be permitted.

RFR
This flag indicates whether the current class is included in the SAF router table. See "ROUTER: SAF Router Table" on page 1250. If any *No* value occurs, there is a mismatch, and `RACROUTE` requests for this class return an *indeterminate* result (`RC=4`).

Max
This field contains the maximum length of profile names in this class. This value is a number in the range 1 to 246.

MxE
Maximum length for use with the ENTITY keyword of the RACROUTE macro.

UACC
This column contains the default universal access for profiles created in this class. This value is for setting the profile UACC during addition of a profile in this class if no UACC is specified on the command. UACC can have any of the following values: ALTER, CONTROL, UPDATE, READ, NONE, or ACEE. The last indication means that RACF uses the default UACC of the ACEE for the user.

User
The class is user-installed (as opposed to IBM-defined).

Id Generic class identifier. This is a number in the range 0 - 255 that is associated with the class name in the Class Descriptor Table and also stored in the `CLASTYPE` field of general resource profiles in the RACF database.

Org
The original order (entry number) of this class in the class descriptor table. The first entry in the table has `ORDER=1`.

NoProf
Profiles cannot be defined in this class.

RaclReq
A `RACLIST` is required for this class.

DataSpc
RACLISTed profiles for this class have been stored in a dataspace.

SeclReq
A security label is required for profiles in this class.

RvrsMAC
Reverse mandatory access checking is required.

EqualMac
Equal mandatory access checking is required.

RaclGlblOnly
The class is RACLISTed due to `RACROUTE GLOBAL=YES` only.

RaclOK
A `RACLIST` is permitted for this class.

GenlOK
A `GENLIST` is permitted for this class.

Signal
An `ENF` signal must be sent when the class is being RACLISTed, NORACLISTed, or RACLIST REFRESHed.

Qu
The number of qualifiers at the start of the profile name that cannot be generic.

Lowercase
The profile name can contain lowercase characters.

AN#S
This column occurs twice. The first one indicates whether the first character of the profile name can be alphabetical (*A*), a national character (*N*), numerical (*#*) or a special character (*S*). The second one applies to characters after the first one.

Same POSIT value
The classes that share the POSIT value with this class. Whenever a SETROPTS command is issued for any class with a specific POSITvalue, it applies to all classes with that value. This field lists all classes in the CDT, not only the active ones.

Class settings detail display

Select any class on the class settings table display to see the detail view. Selection can be done by putting the cursor on the first character of row selection field and pressing ENTER, or by explicitly typing S there and pressing ENTER.

A detail display is shown in Figure 109.

Figure 109. Class SETROPTS settings - Detail display

Line commands on the class settings display

When you use the / line command to ask which line commands are permitted, the following table is shown.

Command	Meaning	Explanation
C	Copy class setting	Copy a static or dynamic class descriptor table (CDT) entry. Commands to create a new CDT profile and CDTINFO segment are generated. Optionally, the following SETROPTS commands are generated: • SETROPTS CLASSACT • SETROPTS GENERIC • SETROPTS RACLIST or SETROPTS GENLIST is generated provided that the settings for the new class allow for SETROPTS RACLIST or SETROPTS GENLIST **Note:** SETROPTS RACLIST and SETROPTS GENLIST are mutually exclusive.
E	Display event logging	"Reporting on general resource events (EV.R)" on page 567
P	Display profiles	"RA.R RESOURCE - General Resource profiles" on page 147
R	Refresh class	Generate a SETROPTS REFRESH command
S	Show additional information	"S - Select" on page 72

RA.H HELPDESK - One-panel help desk options

The menu option **RA.H** (HELPDESK) can be used to perform the most common user administration tasks, and is especially designed for use by a decentralized or centralized help desk. If your installer chose to follow the suggestions in the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*, it can also be started directly from ISPF by typing CKGHELP. The menu is displayed in Figure 110.

```
  Menu   Options   Info   Commands   Setup   Startpanel
--------------------------------------------------------------------------------
                          zSecure Suite - Helpdesk
Option  ===>

 1      List            List RACF profile information
 2      Password        Set a new password
 3      Default         Set the password to the user's default value
 4      Previous        Set the password to the previous value
 5      Resume          Resume a userid after too many password attempts
 6      Disable         Temporarily disable logon for a userid
 7      Enable          Allow user to logon after a Disable
 8      Set default     Define a default password for a userid

Userid  . . . . . ________     (type userid and press enter)
New password  . . .            (type new password)
Verify password . .            (type new password again)
Reason  . . . . . ____________________________________________________
Workflow option . . 1      1. Request  2. Withdraw  3. Approve  4. Deny
```

Figure 110. HELPDESK Menu

For a decentralized help desk, options 6 to 8 would typically be omitted from the panel by setting the access level to *NONE* on SAF resources CKR.OPTION.RA.H options 6 through 8. The setup of the help panel contents can be done using XFACILIT CKR.OPTION.RA.H profiles on a by-user or by-group basis.

Most of the options shown on this panel are familiar to a RACF administrator; the exception is the *default password*. The default password is an installation-defined option added by Security zSecure [1] An additional and inactive password is required that can only be set by selected administrators. This user must have the default password value. A larger group of administrators like the help desk can *apply* the default password. In this way, the administrators can reset the user password to a predetermined value, even if both the original and new passwords are not known to them.

Enter the **Userid** you want to act on, select an option, and enter any additional fields required for that option, then press ENTER.

The following options can be specified on the Help desk panel:

List
List RACF information about this user. For more information, see "LIST" on page 1515 for details.

Password
Set a new password for the user. Type the new password twice in the appropriate fields. The password must always be changed by the user at the next logon.

Default
Set the user password to the default value. If none has been defined yet, you are prompted for one.

Previous
Set the user password to the previous value.

Resume
Resume the user. This operation only succeeds if all `CKGRACF` schedules indicate that the user can have access to the system.

Disable
Change the user schedule so that the user cannot logon. This change can be accomplished by a hard revoke or soft revoke depending on the user authority. If the user has READ access to SYSADMIN, then that schedule name is used for a hard revoke. If the user has access to GRPADMIN but not SYSADMIN, then the GRPADMIN schedule name is used for a soft revoke. Otherwise, a default schedule accessible to the user is employed.

Enable
Change the schedule of the user so that he can logon as far as the help desk user is concerned. Note however that both schedule names GRPADMIN and SYSADMIN must agree before the user can actually work. That is, neither soft-revokes or hard-revokes have been requested.

Set Default
This sets the default password of a user for use by a help desk. This option should therefore not be available to that help desk.

The normal **Request type** for an administrator to use is `REQUEST`. If you are unauthorized to `REQUEST` the action, your installation might permit you to `ASK` for it. That is, add the action to the administrator queue for approval. If you specify `WITHDRAW`, you are attempting to undo a previous `ASK` or `REQUEST`. If an action has not been performed, you can `DENY` it to cancel the operation.

---

1. | Your local security policy might not permit the use of user fields in USER profiles. In this situation, default passwords are not available.

RA.Q QUICK ADMIN - Quick User Administration

The menu option **RA.Q** (QUICK ADMIN) can be used to perform the most common user administration tasks, and is especially designed for use by decentralized group administrators. If your installer chose to follow the suggestions in the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*, it can also be started directly from ISPF by typing CKRQ. The menu is displayed in Figure 111.

```
Menu  Options  Info  Commands  Setup          StartPanel
------------------------------------------------------------------------------
                          zSecure Suite - RACF - Quick admin
Option ===> ____________________________________________________________

1    Password        Set new password for user
2    Resume          Make sure user can work
3    Display         List user definition
4    Modify          Change user definition
5    Connect         Add group to a user
6    Add user        Create new userid from scratch
7    Add user copy   Create new userid like existing model
8    Phrase          Set new password phrase for user

Userid  . . . . . . . . ________  (type userid and press enter)
New password  . . . . .           (type new password, option 1 only)
Verify password . . . .           (type new password again, option 1 only)
Group . . . . . . . . . ________  (type connect group, option 5 only)
```

Figure 111. QUICK ADMIN Menu

Enter the **Userid** you want to act on, select an option, and enter any additional fields required for that option, then press ENTER.

The following options can be specified on the panel:

Password
Set a new password for the user. Type the new password twice in the appropriate fields. The password must always be changed by the user at the next logon.

Resume
Resume the user in RACF. This field does not affect any CKGRACF schedules.

Display
List RACF information about this user which includes the following basic information:

- Identification: name, owner, default group, installation data.
- System access: Current revoke status and active status.
- Statistics: Creation date, last logon (connect) date, last use date.
- All the Connects with each the installation data for each group.

Modify
Change RACF information for this user. This command provides modifiable fields for basic user information: User name, owner, default group, current revoke status, and Connect list. In addition, this command lists each Connect entry with a line command field for copying or deleting the entry.

Connect
Connect the user to the group. This command provides a fast way to create a basic Connect that has USE authority and no other attributes.

Add user
Create a new user. This option opens a data entry panel requesting a name for the user ID (required), a default connect group (required), the owner, a new password (twice), and optionally installation data and a password phrase. When NLS options remove option **RA.Q.8** Phrase from the **RA.Q** display, the password phrase is also removed from this panel. See also the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

Add user copy
Create a new user almost exactly like an existing model user profile. This option opens a data entry panel requesting a different name for the user ID (required), the `userid` for the model user profile, the owner, a new password (required, twice), and optionally different owner, default group, and installation data.

Note: Protected user IDs cannot be created with this function. To create these IDs, use the **Protected** option of the **C** (copy) line command available from option **RA.U**.

Phrase
Set a new password phrase or clear the password phrase for the user.

RA.W Windows - zSecure Visual administration

Use the menu option **RA.W** for selecting users or groups that are marked for deletion by zSecure Visual administrators. The option is only available when the zSecure Visual product is installed and not disabled. The panel shown for this function depends on the product combination and `IFAPRD`*xx*. That is, when only zSecure Visual is installed the panel content is different than it is when both zSecure Visual and zSecure Admin are both installed and active.

If your IBM Security zSecure Admin is installed and active, the **RA.W** function shows the list of users or groups that are marked for deletion. You can selectively confirm or cancel the delete operation for each of these users or groups. Without the IBM Security zSecure Admin component, the `RA.W` function only generates the commands to remove the users or groups. You can still edit the generated commands before you run them.

When both zSecure Visual and zSecure Admin are installed, the following panel is shown:

```
 Menu  Options  Info  Commands  Setup          StartPanel
--------------------------------------------------------------------------------
                          zSecure Suite - RACF - Windows
Command ===> ____________________________________________________________

This panel allows you to select users or groups that are marked for deletion
by zSecure Visual administrators

Show userids that are marked for deletion
Userid  . . . . . . . . ________  (user profile key or filter)

Show groups that are marked for deletion
Group . . . . . . . . . ________  (group profile key or filter)
```

Figure 112. Visual selection panel with zSecure Admin

You can specify the following information on this panel:

Userid
Enter the user ID you want to select. To select more than one user ID, you can specify a filter using the following wildcard values: % to represent one character, or * to represent one or more characters.

The specified value provides the search criteria for selecting user IDs marked for deletion by zSecure Visual administrators. These user IDs are selected by the following command: CKGSCHED=$DELETE.

Userid is mutually exclusive with the Group field.

Group
Enter the group you want to select. To select more than one user ID, you can specify a filter using the following wildcard values: % to represent one character, or * to represent one or more characters.

TThe specified value provides the search criteria for selecting groups marked for deletion by zSecure Visual administrators. These groups are selected by the following command: USRNM=CNGDELET.

Group is mutually exclusive with the **Userid** field.

After you specify the search criteria and press Enter, the panel shown in Figure 113 opens to see the list of users or groups marked for deletion.

```
zSecure All users marked for deletion overview              Line 1 of 4
Command ===> _____________________________________________ Scroll===> PAGE
Type D in front of each user to delete          21 Jun 2005 11:04

__ C##QA003 DINO     QA SUBJECT 003______ C##QA___ C##QA___ ____ ___       X   1
__ C##QA004 DINO     QA SUBJECT 004______ C##QA___ C##QA___ RI__ ___       X   1
****************************** BOTTOM OF DATA ********************************
```

Figure 113. Visual users marked for deletion overview

For a description of the fields displayed, see "User profile tabular display" on page 89.

On this display, typing D in front of a user ID or group ID, depending on the profile option you selected, opens a panel like the one described under option D in "Line commands" on page 54. From that panel, you can generate the commands to remove the user or group. You can also decline the removal of a user ID or group ID by zooming in to the detail display using the S line command) and, on the detail display, deleting the $DELETE schedule by typing D in front of it.

When only zSecure Visual is installed, the following panel is displayed:

```
  Menu  Options  Info  Commands  Setup          StartPanel
--------------------------------------------------------------------------------
                        zSecure Visual Server Admin - RACF - Windows
Command ===> ____________________________________________________________

This panel permits you to select users or groups that are marked for deletion
by zSecure Visual administrators

Generate remove commands for userids that are marked for deletion
Userid  . . . . . . . . C#MXC02_  (user profile key or filter)

Generate remove commands for groups that are marked for deletion
Group . . . . . . . . . ________  (group profile key or filter)
Specify resources to delete
/  Data set and id-specific profiles
Only if previous option selected:
_  RACFVARS profiles and members
/  Data sets and their catalog entries
_  Incl. catalog entries without data sets
_  Incl. uncataloged data sets
Change USERID in Notify fields to   ________  (default is NONOTIFY)
New Owner for non-dataset profiles  ________  (default is SYS1)
```

Figure 114. zSecure Visual selection panel without zSecure Admin

The following fields can be specified on the panel:

Userid
Enter the user ID you want to select. To select more than one user ID, you can specify a filter using the following wildcard values: `%` to represent one character, or `*` to represent one or more characters.

The specified value provides the search criteria for selecting user IDs marked for deletion by zSecure Visual administrators. These user IDs are selected by the following command: CKGSCHED=$DELETE.

`Userid` is mutually exclusive with the `Group` field.

Group
Enter the group you want to select. To select more than one user ID, you can specify a filter using the following wildcard values: `%` to represent one character, or `*` to represent one or more characters.

TThe specified value provides the search criteria for selecting groups marked for deletion by zSecure Visual administrators. These groups are selected by the following command: USRNM=CNGDELET.

Group is mutually exclusive with the **Userid** field.

Data set and id-specific profiles
Selecting this option generates RACF commands to delete any RACF dataset profile which starts with the group ID or user ID. Profiles in other classes which have the group ID or user ID in certain predefined qualifiers are also deleted. If no matching profiles exist, then the delete command fails.

RACFVARS profiles and members
This option controls whether apparent occurrences of user IDs and group IDs in the key or member list of profiles in this class should be considered meaningful, and hence imply (partial) deletion.

Incl. catalog entries without data sets and Incl. uncataloged data sets
You can include or exclude catalog entries without data sets and uncataloged data sets as required. If you receive any inconsistency warnings, investigate them because they can indicate that residues remain, especially for VSAM errors.

Data sets and their catalog entries
This option controls if the data sets and catalog entries implied are deleted too. The ones protected by a profile to be deleted, or unprotected but with an HLQ matching a deleted id are implied.

Change USERID in Notify fields to
This option permits you to enter a USERID to get RACF notifications which would have previously been sent to one of the USERIDS to be deleted.

New Owner for non-dataset profiles
If you delete a user ID or a group ID which was the RACF owner of any profiles, the ownership of these profiles is changed based on the following rules:

- For group data sets, the ownership is changed to the high-level qualifier (HLQ).
- For connect profiles, the ownership is changed to the group and owner specified in this field.

  If you do not specify an owner, ownership defaults to *SYS1*.

After pressing enter, REMOVE commands are generated for the user IDs or groups selected. These are displayed in an ISPF EDIT session:

```
 File  Edit  Edit_Settings  Menu  Utilities  Compilers  Test  Help
-------------------------------------------------------------------------------
EDIT       C#MBMR4.C2R1EF2A.CKR2PASS                     Columns 00001 00072
Command ===>                                               Scroll ===> PAGE
Press PF3, enter R at the cursor location, press ENTER to run these commands
000001  suppress  deldsd
000002  remove user=C#MCX02   /* TEST USER, NO TSO                          *
****** **************************** Bottom of Data ****************************
```

Figure 115. Visual CKR2PASS file

After verifying the commands, press PF3 to return to the results panel and enter an **R** at the cursor location. The remove commands are run, and TSO commands are generated to delete the users or groups. These are displayed in an ISPF EDIT session:

```
 File  Edit  Edit_Settings  Menu  Utilities  Compilers  Test  Help
-------------------------------------------------------------------------------
EDIT       C#MBMR4.C2R1EF2A.CKRCMD                       Columns 00001 00072
Command ===>                                               Scroll ===> PAGE
Press PF3, enter R at the cursor location, press ENTER to run these commands
000001          /* CKRCMD file CKR1CMD complex DINO generated  8 Feb 2005 10:27
000002          /* Commands generated by (RE)MOVE USER/GROUP */
000003         remove C#MCX02  group(C#MCXDEL)
000004         remove CRMCX02  group(C#MCXGRP)
000005         raclink id(C#MCX02 ) undefine(DINO.C#MCX01)
000006         deluser C#MCX02  /* dfltgrp=C#MC     */
****** **************************** Bottom of Data ****************************
```

Figure 116. Visual CKRCMD file

Again, after verifying the commands, press PF3 to return to the results panel and enter an **R** at the cursor location to run the TSO commands. The result of the command execution is displayed in an ISPF BROWSE session.

RA.1 ACCESS - Access Check

Use the **RA.1 Access** option to test the access of a user or group on a dataset or general resource profile. For the DATASET class you can also specify a data set name, to see the access level on the profile covering this data set.

```
  Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                        zSecure Suite - RACF - Access Check
Command ===>

 Specify profile for Access Check
  Class  . . . . . . DATASET_  (DATASET or class)
  Profile  . . . . . SYS1.IPLPARM_____________________________ (EGN mask)
```

Figure 117. Access check panel

This example queries what access the user ID C##BJTI has on the resource SYS1.IPLPARM in the DATASET class. This query generates the CKGRACF command shown on the confirmation panel. The confirmation panel shown in Figure 118 is shown based on the Confirmation setting on the SETUP CONFIRM panel.

```
                          zSecure Suite - Confirm CKGRACF command
Command ===> ____________________________________________________________________
Confirm or edit the following CKGRACF command
ACCESS C##BJTI DATASET SYS1.IPLPARM

Command execution . 2  1. EXECUTE RACF command
                       2. EXECUTE CKGRACF command (allows use of Reason)
                       3. ASK administrator to execute CKGRACF command
                       4. REQUEST CKGRACF command for later execution
                       5. WITHDRAW CKGRACF command

Reason . . . . . . .  ____________________________________________________

Press ENTER to continue or END to cancel the CKGRACF command
```

Figure 118. Access command confirmation panel

After pressing **Enter**, the command is run regardless of the SETUP CONFIRM **Action on command** setting. The result of the command is shown in a browse panel. In this example, a fully qualified data set name was used which results in a panel showing the access to the profile covering this data set.

RA.2 QUEUED - Queued commands

Queued commands are CKGRACF commands that are either subject to multiple-authority or are timed or temporary. CKGRACF is the APF-authorized component of IBM Security zSecure Admin. This function provides support for managing the following command-related services:

- Group administration based on function-specific profiles.
- Manage the *multiple-authority* option.
- Delay execution of a command until a future date using timed commands.
- Request temporary commands. For example, create a command that reverses the effects of a command at some later date.

Use Option **RA.2** to find and review queued commands, and then act on them. If your installation does not use these functions, you can skip this queued commands topic.

Multiple Authority

The multiple-authority requirement of a CKGRACF command can be SINGLE, DUAL or TRIPLE; if it is DUAL or TRIPLE, this means that after the initial REQUEST by an authorized user, it is queued for approval by one or two other authorized users.

The multiple-authority requirement of such a command is determined by the multiple-authority setting in the target profile or, if it contains none, the installation-wide default.

Unauthorized users might be permitted to ASK for (as opposed to REQUEST) a command by the installation. This always queues the command for approval. (However, ASK is not supported for TRIPLE authority requests.)

The Approval Queue

The approval queue contains requests that are not yet fully authorized. When you ASK or REQUEST a command, and it is queued for approval, the status asked (A) or requested (R) is assigned. At this stage the requestor can WITHDRAW the command which removes it from the approval queue and generates an audit trail entry. An authorized user who has not yet authorized the command can APPROVE it. Depending on the applicable multiple-authority setting, the command can now either be fully authorized or require further authorization.

If the command is fully authorized, it is removed from the approval queue. If it is a timed command specified to run at a future date, it is added to the execution queue. An Immediate command is run and an audit trail entry is generated.

If you APPROVE a command that has the multiple-authority setting, the command is moved to the next approval stage. For example, if the command is a TRIPLE authority command, the first approval is followed by a second approval request (SR) stage, and then a third approval *Request* stage.

An authorized user who has not yet taken part in authorizing the command can DENY it. If a command is denied, it is removed from the approval queue and an audit trail entry is generated. If a command has been queued for approval, but no action is taken within a reasonable time, the command expires. It is removed from the approval queue and an audit trail entry is generated. To keep a request longer than usual, an authorized user can HOLD it. Held commands then move to the second held (SH) or complete held (CH) stage.

The Execution Queue

The execution queue contains timed commands that have been approved, but for which the requested start date has not been reached yet. They have the status pending (P).

A timed command is a command that contains an "AT *date*" qualifier. It can be either permanent or temporary, depending whether it also contains a "FOR *days*" or "UNTIL *date*" clause.

When the start date is reached, the command is removed from the queue and run, and an audit trail entry is generated. If the command is a temporary one, a permanent timed command is queued to the execution queue with the end date of the original one as its start date to reverse its effect in time. Such a reverse has the pending reverse (PR) status.

Reviewing queued commands

Selecting **RA.2** Queued brings you to the panel shown in Figure 120.

```
 Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - RACF - Queued
Command ===>

Show only profiles that fit all of the following criteria:
Class name  . . . . ________     (class or filter)
Profile pattern . . SYSS.**_____________________________________ (EGN mask)
Complex . . . . . . ________     (complex name or filter)

Show only profiles with
 1  1. Queued commands requiring action
    2. Commands in the execution queue
    3. Withdrawn, denied or expired commands
    4. Any queued commands

Enter "/" to select option(s)
 _  Show all queued commands within selected profiles
```

Figure 120. Queued commands selection panel

The Class name, Profile pattern, and Complex field can be specified to limit the search for queued commands. You can specify a search filter using the generic characters % and *. Use the next option to specify selection criteria for the queued commands you are interested in. You can select using the following command type criteria:

- Outstanding command requests.
- Commands authorized to run at future date.

- Commands that have been denied.
- All queued commands, including those commands that have been denied.

Most of the selection criterion for commands also determines what commands are shown for each selected profile. However, you can choose to see all the commands within the selected profiles by selecting the option for all queued commands.

Figure 121 shows a sample display panel.

```
zSecure Admin PROFILE display                          Line 1 of 1
Command ===>                                           Scroll===> CSR

   Class    Profile key                       Expires LastReq LastChg
s_ USER     C##QA048 NOMEN NESCIO              22Dec11 15Dec11 15Dec11
****************************** BOTTOM OF DATA ********************************
```

Figure 121. Queued commands profile display

Each line lists the profile class, the profile key, the first date a queued command expires, the latest date a command was requested, and the latest date a command was changed including requests. For User profiles the user name is shown as well, while for Group profiles the installation data is included. You can sort the display on any column using the SORT command. For example, to sort commands based on the date before which they must be acted upon, type `SORT 'Expires'` behind the **Command ==>** prompt.

After a profile has been selected, the following detail panel is shown.

```
zSecure Admin PROFILE display                                  Line 1 of 8

```

Figure 122. Queued commands detail display

The detail panel shows the multiple-authority requirement, if set, and the queued commands. The status of the queued command is indicated between parentheses.

Table 119 lists the possible status values for a queued command. Depending on the command status, you have options to run different line commands. The following table indicates which line commands are available based on the status value of the queued command.

Table 119. Queued commands - status types

Abbreviation	Command status
(A)	Asked . This command is waiting to be approved or denied. The available line commands are **A**, **C**, **D**, **H**, **I**, **R**, and **S**.

Table 119. Queued commands - status types (continued)

Abbreviation	Command status
(CA)	Complete approve. This command has been approved and run. The actions permitted are **C**, **I**, **R**, and **S**.
(CD)	Complete deny. This command has been denied and cannot be run. The actions permitted are **C**, **I**, **R**, and **S**.
(CH)	Complete hold . The command is on hold. It can either be approved or denied. The actions permitted are **A**, **C**, **D**, **H**, **I**, **R**, and **S**.
(E)	Expired This. Command can no longer be completed. The actions permitted are **C**, **I**, **R**, and **S**.
(P)	Pending This. Command has been approved; it is now waiting for its execution date. The actions permitted are **C**, **D**, **I**, **R**, and **S**.
(PR)	Pending reverse . Command is the reverse of a temporary command that has been run. It is waiting for its execution date–that is, the end date for the temporary command. The actions permitted are **C**, **I**, **R**, and **S**.
(R)	Requested. Command is waiting to be approved or denied. The actions permitted are A, C, D, H, I, R, and S.
(SA)	Second approve . This command has been approved, but must be approved again (complete approve) before being run. The actions permitted are **A**, **C**, **D**, **H**, **I**, **R**, and **S**.
(SD)	Second deny . This command has been denied, and the command cannot be run. The actions permitted are **C**, **I**, **R**, and **S**.
(SH)	Second hold . This command is on hold and can be approved to pass on to the *complete* stage or denied. The actions permitted are **A**, **C**, **D**, **H**, **I**, **R**, and **S**.
(W)	Withdrawn . This command request has been withdrawn, and cannot be run. The actions permitted are **C**, **I**, **R**, and **S**.
(X)	Executed . This command has been approved and run. The actions permitted are **C**, **I**, **R**, and **S**.

The following action characters (line commands) can be used to work with the queued commands.

Table 120. Queued commands - available line commands

Action character	Effect
A	Approve a queued command.
C	Display a filled-in REQUEST panel to request a new command.
D	Deny or withdraw the queued command.
H	Hold a queued command.
I	Display an empty REQUEST panel to request a new command.

Table 120. Queued commands - available line commands (continued)

Action character	Effect
R	Create a copy of the queued command (repeat the request).
S	Display the queued command in more detail.

When you run the **C** line command, a completed REQUEST panel is shown. The panel shown depends on the type of queued command that is repeated. If the queued command pertains to schedules, you get a dedicated panel. If it is a PERMIT, CONNECT or REMOVE command, you get a general CKGRACF CMD panel. Another panel is shown for requests related to passwords and soft-resumes.

When you issue the **I** line command on a group profile display, you are prompted with a dedicated Connect/Remove panel. For a DATASET profile, the PERMIT panel opens. For a user profile, you are prompted to specify whether you want to issue a SCHEDULE command or a command related to passwords.

Figure 123 shows the Request a password panel.

   7. Make Protected

Request type  . . . . _  A(sk), R(equest) or W(ithdraw)
```

Figure 123. Request a command panel - password commands

Userid
The user you want to request a command for. Specify a valid user ID, without filter patterns.

Select action
Choose one of the numbered actions.

1. New password
This option can be used to reset the password to a new value. When this action is selected, you have to specify the new password twice.

2. Interval
This option can be used to set the password interval. Enter 0-254 for a specific password interval or N for no interval. When no value is entered the SETROPTS password interval setting is used.

3. DEFAULT password
This option can be used to set the password to a default value.

4. PREVIOUS password
This option can be used to set the password to the previous value.

5. RANDOM password
This option can be used to set the password to a random value.

6. Resume only
This option can be used to resume the user ID.

7. Make Protected
This option can be used to make this user ID protected from revoke due to too many password attempts.

Options
Each of these options can be selected by placing a '/' in front of them.

Password expired
Specifies that you want the user to change the password at the next login.

Resume userid
Specifies the user ID to be resumed. This option can be specified without resetting the password.

Ignore pw history
This option can be used to disable the history check performed by CKGRACF when a password is set.

Bypass pw rules
This option can be used to disable the password rule check performed by CKGRACF when a password is set.

Bypass pw exits
This option can be used to disable the ICHPWX01 exit call from CKGRACF when a password is set.

Request type
A CKGRACF parameter for multiple-authority, normally set to REQUEST. In some installations, end users might be permitted to ASK for permissions. A request that is not authorized to be run immediately shows up in the administrator approval queue for review. To retract a request in the approval queue (either due to ASK or because of a DUAL or TRIPLE authority requirement) specify WITHDRAW.

The Manage User schedules panel can be used to specify scheduled enabled or disabled periods; to list all scheduled revoke/resume events; or to wipe scheduled events. The panel is displayed in Figure 124 on page 191. Use option **1** to list all CKGRACF settings for the user ID, including all scheduled events and the overall schedule. Use the other options to add or wipe scheduled events. Use the **MS** line command to work with scheduled events.

```

2  Enable       Specify date(s) when user should be able to logon
3  Disable      Specify date(s) when user should not be able to log on
4  Wipe         Remove scheduled events at specified date(s)

Userid  . . . . . . . C##BSG1
Schedule  . . . . . . ________

Start date  . . . . . __________  End date  . . . . . . __________
                                  Number of days  . . . ___

Enter reason below
____________________________________________________________________________
```

Figure 124. Manage User Schedules

Schedule
The schedule name. If you use any of the options **2** to **4**, the schedule name is required.

Start date
The start date, required for options **2** to **4**. A date is specified in the format 01JAN1995.

End date
Optional end date. If specified, the scheduled enabled or disabled period extends from the start date up to (and including) the end date. Cannot be combined with 'Number of days'.

Number of days
Optional number of days an enabled/disabled period lasts. Cannot be combined with 'End date'.

Reason
Optional reason for the scheduled action (options **2** and **3**) or optional wipe reason (option **4**).

A queued command can contain both SCHEDULE and PASSWORD parameters. If you repeat such an entry, both panels are presented. When you build a command string for a single user, you cannot alter the **Userid** on the second panel if you already specified a command on the first panel. To avoid confusion you are not permitted to alter the **Request type** on the second panel in that case either.

Figure 125 shows the dedicated REQUEST CONNECT/REMOVE panel.

```
                      zSecure Suite - Request connect/remove
Command ===> ____________________________________________________________

Specify Group and User:
Group          ===> SYS1____         Connect/Remove ===> CONNECT
Userid         ===> ________

Request parameters:
Start date     ===> _________        End date       ===> _________
Number of days ===> ___

Request type   ===> R                A(sk), R(equest) or W(ithdraw)
```

Figure 125. Request connect/remove panel

Group
The group to connect to or remove from.

Connect/Remove
Indicates if the request is for connecting the user to the group or removing the connection.

Userid
The user to connect or remove from the Group.

Start date
The start date, required for options **2** to **4**. A date is specified in the format 01JAN1995.

End date
Optional end date. If specified, the scheduled enabled or disabled period extends from the start date up to (and including) the end date. Cannot be combined with 'Number of days'.

Number of days
Optional number of days an enabled/disabled period lasts. Cannot be combined with 'End date'.

Figure 126 shows the dedicated REQUEST PERMIT panel.

```
                        zSecure Suite - Request permit
Command ===> ____________________________________________________________

Specify profile:
Class . . . . . . . DATASET
Profile . . . . . . 'C##BFK1.CNRACF%.CKRCMD'
Generic . . . . . . ___        (Yes for fully qualified generic, default No)

User or group on access list to process (specify new access or enter Delete):
User/group  . . . . C##B____
Access  . . . . . . ALTER__    (Delete/None/Execute/Read/Update/Control/Alter)

Request parameters:
Start date  . . . . 01JAN2005_       End date . . . . .  __________
                                     Number of days . .  30_

Request type  . . . R                A(sk), R(equest) or W(ithdraw)
```

Figure 126. Request permit panel

Class
The class of the profile you want to grant a permit to or revoke a permit from.

Profile
The profile you want to grant a permit to or revoke a permit from.

Generic
If the profile is a fully qualified generic, which is a generic profile that contains no generic characters, specify YES in this field. In all other cases, you can leave this field blank.

User/group
Specify the user or group id to grant a permit to the profile to or take away a permit to the profile from this field.

Access
Specify the desired level of access in this field. To remove an existing permit rather than grant a new one, specify DELETE in this field.

Start date
The start date, required for options **2** to **4**. A date is specified in the format 01JAN1995.

End date
Optional end date. If specified, the scheduled enabled or disabled period extends from the start date up to (and including) the end date. Cannot be combined with 'Number of days'.

Number of days
Optional number of days an enabled/disabled period lasts. Cannot be combined with 'End date'.

Figure 127 shows the generic REQUEST CMD panel.

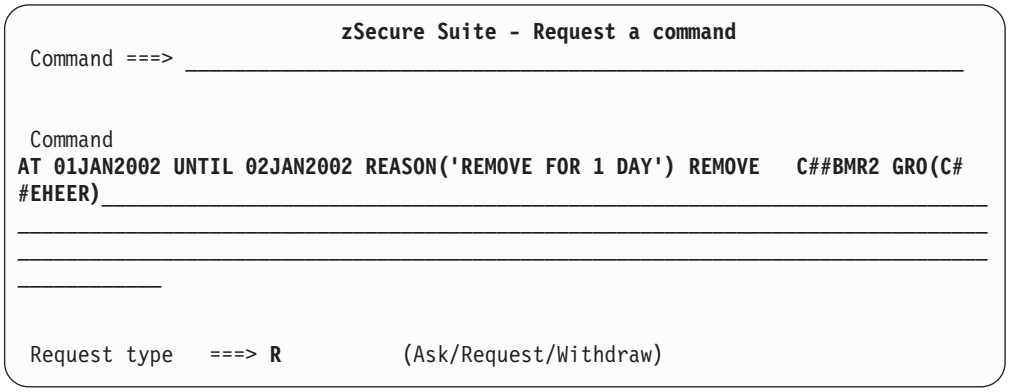

Figure 127. Request a command panel

Apart from the **Request type**, specify the entire CKGRACF CMD. You can enter fairly long commands; in a display of this width you can use in fact several lines, not just one.

RA.3 Reports - Reports with profiles and resources

Option **RA.3** Reports offers a number of special reports.

```
 Menu  Options  Info  Commands  Setup          StartPanel
------------------------------------------------------------------------------
                        zSecure Suite - RACF - Reports
Option  ===>

1    Profiles        Any profiles fitting mask/qualifier with their data sets
2    Non redundant   Data set profiles different from less specific profiles
3    Redundant       All data set profiles, mark if non-redundant (as in 2)
4    Permit/scope    User/group on access list, or access by any means
5    Out of group    Group data sets accessible to users outside the group
6    Non default     Data sets with more in access list than 'owner has alter'
7    Match           Find profiles that cover a data set or resource
8    Group tree      Group tree display
9    USERDATA        Display and action on profiles with USERDATA
A    Tapevol         Tapevol profile overview
B    RACFvars        RACF variable profiles
C    APPL            Application profiles
D    JES/328X        Jes/328X definitions and log data sets
E    SDSF            SDSF command and display authorities
F    JES2            Access to JES2 resources
G    Compare users   Compare access and/or connect
```

Figure 128. RACF Reports menu

These reports come in different categories:

- Reports that combine data from several profiles and from profiles and resource information are available from options **RA.3.1** - **RA.3.6**, **RA.3.D**. For additional information about these reports, see `REPORT <reporttype>` in Chapter 13, "SELECT/LIST Fields," on page 953.
- Special function panels are available from options **RA.3.7** through **RA.3.9**, and **RA.3.G**.
- Class-specific profile query panels are available from options **RA.3.A** through **RA.3.C**.
- Application-specific overview panels are available from options **RA.3.E** and **RA.3.F**.

Note: Reports of special interest for status auditing are available from option **AU.S**. These reports include special reports on the protection of sensitive data sets, APF-authorized programs, Program Access to Data Sets (PADS) and STCs. For more information, see "STATUS AUDIT - RACF resource" on page 316 and the overviews of the GLOBAL and STARTED classes described in "STATUS AUDIT - RACF control" on page 266.

The line commands available from the **RA.R** menu option panels depend on the `ENTITY` type (user, group, data set, or general resource profile). The commands listed on a panel are the same line commands listed for the standard displays for these entity types, except for reports that show combined data from multiple profiles or from profiles and resources. On these reports, either the default line command set as explained in Table 18 on page 54 applies, or the specific options are explained separately.

Table 121 provides an overview of the RACF Report menu options with references to more detailed information.

Table 121. RA.R Report menu options

Menu option	Purpose
"RA.3.1 Profiles - Profiles with their data sets" on page 196	Reports on selected profiles in the DATASET and general resource classes, along with their access list, UACC, and auditing requirements.

Table 121. RA.R Report menu options (continued)

Menu option	Purpose
"RA.3.2 Non redundant - Data set profiles different from less specific profiles" on page 201	Understand what data sets are protected and how they are protected. The report filters out profiles that are considered redundant because they provide the same access as the next most specific profile, and then reports on the data sets for the most specific remaining profiles.
"RA.3.3 Redundant - Finding and removing redundant profiles" on page 205	Report on redundant profiles that are candidates for removal because they provide the same access as another more specific profile.
"RA.3.4 Permit/Scope - Report access of a user or group" on page 207	Overview of all resources a user or group has access to. The access can be explicit access through a `CONNECT` or `PERMIT`, or implicit access through the UACC.
"RA.3.5 OUT OF GROUP - Group data sets that can be accessed from outside the group" on page 212	Provides information about group data sets that have the potential to be accessed by users or groups outside of the group.
"RA.3.6 Non default - Reporting nonstandard data set access lists" on page 214	Overview of profiles that have access control that does not comply to the default access control specified in security policy.
"RA.3.7 MATCH - Find profiles that cover a data set or resource" on page 216	Identify all profiles that can cover a specified data set or resource name. RACF uses the most specific profile to protect a resource or data set. However, you can use this display to see what *other* profiles might also protect the resource.
"RA.3.8 GROUP TREE - Group tree display" on page 217	View all group profiles in a format indicating the group-tree structure. You can use selection criteria to specify parts of the group tree to select or exclude.
"RA.3.9 USERDATA - User data management" on page 219	Find and view installation-defined User fields and change the `userdata`.
"RA.3.A TAPEVOL - Tape Profile Overview" on page 222	Shows information about `TAPEVOL` profiles that fit the selection criteria. This report is a variant of the General Resource Profiles panel geared towards the `TAPEVOL` class.
"RA.3.B RACFVARS - RACF variable profiles" on page 225.	Shows information about RACF variables profiles that fit the selection criteria that you specify.
"RA.3.C APPL - Application profiles" on page 227	Shows a list of all RACF profiles in the `APPL` class. These profiles control the access permissions to some applications like IMS™ or CICS. On the resulting display panel, you can use action characters to work with the profiles.
"RA.3.D JES/328X - Jes/328X definitions and log data sets" on page 228	Work with JES/328X related dataset profiles and, optionally, list the data sets they cover such as the JES/328X log data sets.
"RA.3.E SDSF - SDSF command and display authorities" on page 228	See an overview of all profiles that affect SDSF security. Line commands are available to work with the profiles.
"RA.3.F JES2 - Access to JES2 resources" on page 229	See an overview of all profiles that affect JES2 security. Line commands are available to work with the profiles.

Table 121. RA.R Report menu options (continued)

Menu option	Purpose
"RA.3.G Compare users - Compare access and/or connect" on page 230	Compare user ID access in two different ways: Through permits with an option to include group permits, or compare connects for up to four user IDs.

RA.3.1 Profiles - Profiles with their data sets

The **RA.3.1 Profiles** menu option shows selected profiles in the DATASET and general resource classes, along with their access list, UACC, and auditing requirements. In this report, you can request the names of data sets covered by the profile to be added. In contrast to the LD DSNS parameter in RACF, this report also includes uncataloged data sets on disk, uncataloged migrated data sets, tape data sets from a tape management catalog, the original data set names for backed-up discrete profiles, and single-qualifier data set names. Because of the cross referencing capability this REPORT PROFILES offers a different approach from a standard profile view in RACF. However, some line commands available on the standard RACF profile view are not supported from this zSecure profile view.

```
   Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                         zSecure Suite - RACF - Reports Profiles
Command ===>

Show profiles that fit all of the following criteria:
Class name  . . . . ________     (class or filter)
Profile pattern . . SYS*.**_____________________________________ (EGN mask)
High level qual . . ________     (qualifier or filter)
Complex . . . . . . ________     (complex name or filter)

Enter "/" to select option(s)
/  Show data sets covered by each profile
   _  Including data sets on scratch tapes
_Show general resources covered by each profile

_  Output in print format
   _  Start each user or group on a new page
```

Figure 129. Report profiles selection panel

The following selection criteria are supported.

Table 122. Profile Report - available selection criteria

Selection criteria	Description
Class name	Limit to this class, or classes matching this filter
Profile pattern	Limit to profiles matching this pattern.
High level qual	Limit to profiles with this HLQ as modified by `ICHCNX00` (if present), or an HLQ matching this filter
Complex	In a complex with this name, or a matching complex if a filter is used.

The following options customize the output.

Table 123. Profile report - options for customizing output

Option	Description
Show data sets covered by each profile	Include the data set names covered with each profile
Including data sets on scratch tapes	Include even those data sets that can be overwritten at any time because the tapes they are on are in scratch status. This option is only meaningful if you asked for inclusion of data sets in the first place.
Show general resources covered by each profile	Include sensitive resources and a supported subset of other general resources covered by the resource profile (zSecure Audit only)
Output in print format	Generate output in a printable format instead of in an ISPF table
Start each user or group on a new page	Issue a form feed whenever a new HLQ is started. This option is only meaningful if you are generating output in print format.

A sample class selection display is shown in the following figure.

```

Figure 132. Report profile detail display

The following fields of interest are shown.

Table 126. Profile Report - detail display fields of interest

Field	Description
Type	Shows the profile type for profiles (the first line). For other resources, shows the type of data set or resource. For the resources (the other lines), the type of data set or resource. Available types are listed in Table 127 on page 200.
Profile name	The profile name, followed by the names of the data sets or resources covered (if requested).
Volume	The volume the profile applies to/the data set resides on.
Full profile name	The full profile name up to 246 characters.
Id	Userid or group ID that has access on this profile.
Access	The access level.

Table 126. Profile Report - detail display fields of interest (continued)

Field	Description
Via	Condition under which access applied (for a conditional entry): class and profile name, or blank.
Name	For a user ID in the Id column the user name is shown here.
Data	Installation data for the user or group.

The data set types that can be shown are listed in the following table.

Table 127. Profile Report - Data set types

Data set type	Description
nvsam	Non-VSAM disk data set, migrated if the volume status is `MIGRAT` for `HSM` or `ABR`, or archived if the volume is ARCIVE for `DMS`. This information is obtained from the VTOC for data sets on disk, the HSM MCDS and the `ABR` ACF for migrated data sets, and the `DMSFILES` data set for archived data sets. The information is not derived from the catalog entries.
clustr	VSAM cluster (catalog entry). The volume listed is the volume of the catalog. The source for the cluster names can be one of the following: a catalog, an `HSM MCDS`, `ABR ACF`, `DMS DMSFILES` data set, or `VVDS`.
bkpclu	Backup of a VSAM cluster. Normally, this is only listed below a backed-up discrete profile (for example, a discrete profile with a system-generated name). The source for the cluster name is either the `HSM BCDS` or a `DMS DMSFILES` data set.
index	Index component of a VSAM cluster residing on the indicated DASD volume.
data	Data component of a VSAM cluster residing on the indicated DASD volume.
aixix	Index component of a VSAM alternate index residing on the indicated DASD volume.
aixda	Data component of a VSAM alternate index residing on the indicated DASD volume.
migcl	Migrated or archived VSAM cluster. This is listed below a cluster entry instead of the components. The volume is equal to MIGRAT or ARCIVE.
clust	Backup of VSAM cluster. This is listed below a bkpclu entry instead of the components. The volume is equal to MIGRAT or ARCIVE.
gag	Base name of a GDG (Generation Data Group), obtained from a catalog.
cnntap	Cataloged, non-managed tape file, on a non-managed volume.
unntap	Uncataloged, non-managed tape file, on a non-managed volume. The source for such an entry is probably the `TVTOC` of a `TAPEVOL` profile.
cmmtap	Cataloged, managed tape file on a managed, nonscratch tape volume.
ummtap	Uncataloged, managed tape file on a managed, nonscratch tape volume.
cnmtap	Cataloged, non-managed file on a managed, non-scratch volume. This means that the catalog entry conflicts with the tape management information.
unmtap	Uncataloged, non-managed file on a managed, non-scratch volume. The source for such an entry is probably the `TVTOC` of a `TAPEVOL` profile.
cnstap	Cataloged, non-managed file, on a managed volume in scratch status.
unstap	Uncataloged, non-managed file, on a managed volume in scratch status. The source for such an entry is probably the TVTOC of a `TAPEVOL` profile.

Table 127. Profile Report - Data set types (continued)

Data set type	Description
secvol	Secondary volume of a multi-volume data set.
sensr-r	General resource (not a data set) that is sensitive if read access is permitted.
sens-w	General resource profile that is sensitive if update access is permitted.
sens-a	General resource (not a data set) that is sensitive if alter access is permitted.
priv	General resource (not a data set) that gives the user some privilege.

In print format, the report looks like the report shown in the following figure.

Figure 133. Report profile print format

Notes:

1. Listing the data sets covered requires a CKFREEZE file, and furthermore that *VSAM data sets are not listed if no catalog dump was included.*
2. For advanced users: if you want to write your own REPORT_PROFILES query, the data sets covered can be included by means of the REPORT DATASETS command; to include data sets on scratch tapes as well, also add the SCRATCH keyword.

RA.3.2 Non redundant - Data set profiles different from less specific profiles

The **RA.3.2 Non redundant** menu option is designed to help you understand what data sets are protected and how they are protected. The report filters out profiles that are considered redundant because they provide the same access as the next most specific profile. The report includes he data sets for the most specific remaining profiles. The criteria for determining whether profiles are redundant are explained in "RA.3.3 Redundant - Finding and removing redundant profiles" on page 205.

```
   Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                          zSecure Suite - RACF - Reports Non redundant
Command ===>

Show profiles that fit all of the following criteria:
Profile pattern . . _____________________________________________________ (EGN mask)
High level qual . . C##BJTI_     (qualifier or EGN mask; reduces time)
Complex . . . . . . ________     (complex name or filter)

Enter "/" to select option(s)
/  Show datasets covered by each profile
   _  Including datasets on scratch tapes

_  Output in print format
   _  Start each user or group on a new page
```

Figure 134. Report Non redundant selection panel

The following selection criteria are supported.

Table 128. Non-Redundant Profile Report - selection criteria

Selection Criteria	Description
Profile pattern	Limit to profiles matching this pattern.
High level qual	Limit to profiles with this HLQ as modified by ICHCNX00 (if present), or an HLQ matching this filter
Complex	In a complex with this name, or a matching complex if a filter is used.

The following options customize the output.

Table 129. Non-Redundant Profile Report - custom output options

Option	Description
Show data sets covered by each profile	Include the data set names covered with each profile
Including data sets on scratch tapes	Include even those data sets that can be overwritten at any time because the tapes they are on are in scratch status. This option is only meaningful if you asked for inclusion of data sets in the first place.
Output in print format	Generate output in a printable format instead of in an ISPF table
Start each user or group on a new page	Issue a form feed whenever a new HLQ is started. This option is only meaningful if you are generating output in print format.

A sample display is shown in Figure 135.

```

****************************** BOTTOM OF DATA ********************************
```

Figure 135. Report NONREDUNDANT profile level display

In this example, the only profile in the query results for the HLQ specified of interest is C##BJTI.**, which is non-redundant because a more generic profile does not exist to take over its role.

The following fields of interest are shown.

Table 130. Non-redundant Profile Report - field descriptions

Field	Description
Complex	The name of the complex
Timestamp	The date and time to which the information pertains
Profiles	The total number of profiles selected
Qual	The first qualifier of this set of profiles (after ICHCNX00 processing)
Profiles	The number of profiles selected with that HLQ
Type	The profile type
Volume	The volume the profile pertains to (if volume-specific)
Profile name	The profile name
First reason	Indicates why this profile is selected. See Table 131.
UACC	The Universal Access of the profile
S/F	The effective success and failure audit levels (separated by a blank).
Era	The Erase-on-scratch settings of the profile

Table 131 lists the reasons that a profile can be considered non-redundant.

Table 131. Non-redundant Profile Report - reasons for profile selection

Reason for selection	Description
- candidate -	This is a generic profile or entry in the global access table that was the most specific matching generic for one of the profiles considered non-redundant.
- redundant -	This field is only present if you requested REPORT REDUNDANT. It marks all profiles that were considered redundant.
Access	The access level of a user or group in the access list of this profile was different from the access level in the access list of the candidate profile for the same identity (user or group), and it was not overruled anyway by an entry in the global access table. The entry is one of the entries marked with an arrow.
Audit	The audit requirements are different from the candidate generic profile.
Erase	The erase-on-scratch requirement is different from that of the candidate generic profile. These profile requirements are not considered if the ERASE(ALL) or NOERASE global options are active.
Extra group	The access list of this profile contains a group that is not present on the access list of the candidate generic profile. It is one of the entries marked with an arrow.
Missing group	The access list of this profile does not contain a group that is present in the access list of the candidate generic profile. You must look up the candidate profile access list to see which group. No arrow is present.

Table 131. Non-redundant Profile Report - reasons for profile selection (continued)

Reason for selection	Description
Missing user	The access list of this profile does not contain a user ID that is present in the access list of the candidate generic profile. That user ID is also not given the same access through a Connect. You must review the candidate profile access list to see which group has the missing user ID. No arrow is present.
No generic	There is no matching generic to serve as candidate.
Undefined id	There is an extra user or group present in the access list that is not present in the access list of the candidate generic profile. However, the user or group was not defined.
Used as model	The profile is used as a model on a USER or GROUP profile and hence not redundant.
User no connect	Might also be called Extra User. A user ID is present in the access list that is not present in the access list of the candidate profile. Nor does that user have a connection to any of the groups present in the access list of the candidate generic profile. The user ID is indicated by an entry marked with an arrow.
User privileged	A user ID is present in the access list that is given more access than the equivalent entry in the access list of the candidate profile, which is either the user ID or the connect group giving the highest access. The user ID is indicated by an entry marked with an arrow. You have to look at the candidate profile access list to find the access level involved.
User restricted	A user ID is present in the access list that is given less access than the equivalent entry in the access list of the candidate profile, either the user ID or the connect group giving the highest access. The user ID is indicated by one of the entries marked with an arrow. You must review the candidate profile access list to find the access level involved.
Universal access	UACC is different from the candidate profile UACC.

A detail display is shown in Figure 136.

Figure 136. Report NONREDUNDANT detail display

The following fields of interest are shown.

Table 132. Non-redundant Profile Report - detail display fields

Field	Description
Type	For the profile (the first line), the profile type. For the data sets (the other lines), the type of data set; see the table in "RA.3.1 Profiles - Profiles with their data sets" on page 196.
Volume	The volume the profile applies to/the data set resides on.
Profile name	The profile name, followed by the names of the data sets covered (if requested).
Complex	The complex name
UACC	The universal access level
S/F	The effective success and failure audit levels (separated by a blank).
Erase	Erase-on-scratch setting
Owner	The profile owner
Dif	Indicates whether this access list entry makes a difference. This column contains an arrow if the access ID is listed for another reason other than being redundant.
Id	Userid or group ID that has access on this profile
Access	The access level
Via	Condition under which access applied (for a conditional entry), or blank
Name	For a user ID in the Id column the user name is shown here
Data	Installation data for the user or group

Figure 137 provides an example of the output in print format.

Figure 137. Report NONREDUNDANT print format

RA.3.3 Redundant - Finding and removing redundant profiles

Use the **RA.3.3 Redundant** menu option for reporting on the access list of dataset profiles to identify redundant profiles that can be removed. The report includes data set profiles in the following categories:

- Profiles not covered by a less specific generic profile.
- Profiles covered by a less specific generic profile where the `WARNING` `AUDIT`, or `ERASE` (if active globally) settings are different.
- Profiles where the access list is different so they cannot be considered similar.

  Access is considered similar if the access list contains the group to which the dataset belongs with a lower level than present in GLOBAL DATASET member `&RACGPID.*` (no EGN), `&RACGPID.**` or `&RACGPID.*.**` (EGN). Access is also considered similar if a user ID is present on the discrete profile access list with an access that is also granted through one of the groups to which the user ID is connected.

Redundant profiles are identified with a `- redundant -`.

A sample display is shown in Figure 138. For additional information about the report and how to interpret it, press F1 on the panel for help.

```

Figure 138. Report REDUNDANT profile level display

This panel shows two separate profiles, but counts three. The middle entry C##BJTI.**, which is the same as the one shown in Figure 134 on page 202, is not redundant because it is a top-level profile (*No generic*). The last entry shows the other, redundant, profile C##BJTI.RE.DUN.DANT.**. The first entry shows that C##BJTI.** is a -candidate- profile, which means that this profile might take over the role from one or more profiles flagged redundant if they were removed.

If the administration product zSecure Admin is installed and not disabled (that is, not only zSecure Audit for ACF2), then the selection panel for this option provides an extra output option *Remove redundant profiles* that means no report is to be generated at all, but instead the REMOVE REDUNDANT function is to be performed. This function generates the RACF commands to remove all profiles marked as redundant in the analysis.

This REMOVE REDUNDANT function is designed specifically to aid in the conversion from ADSP to generic profiles. When you use this function, it automatically generates commands to delete discrete profiles that provide *equivalent* access to the access provided by the combination of the most specific matching generic data set profile and the most specific matching global access table entry (if present).

If you use Automatic Backup and Recovery (ABR) with the PROFKEEP option, be aware that on restore of a non-VSAM data set that must be recreated, the ABR function requests a default discrete profile to be created through ADSP if its RACF indicated bit was set on migration. In addition, this RACF indicated bit is only available on the migration tapes which currently are not checked. Instead, it is assumed that an existing discrete profile applies. If a data set is already allocated, ABR prevents the restore unless the RACF indicated bits match. Therefore, if you are converting from ADSP to generic profiles, consider the implications regarding ABR and take them into consideration when you are reviewing the remove profile commands generated by the REMOVE REDUNDANT function.

For a profile to be considered *redundant*, three profile properties are checked:

1. Access requirements (access list, conditional access list, and universal access).
2. Audit requirements (failure audit level, success audit level).
3. Erase-on-scratch requirement.

The first two items are simply compared to those of the most specific matching generic profile, called the *candidate* profile. They must be equal before the profile is considered redundant. However, the *erase-on-scratch* requirement is not checked if the system wide option ERASE(ALL) or NOERASE is active.

The access requirement comparison is more complicated. Simplest is the *universal access* (UACC) comparison. For a profile to be considered redundant, its UACC must either be equal to that of the candidate profile, or less than ALTER and at the same time less than or equal to the most specific matching entry of the Global Access Table (that is, a member of the DATASET profile in class GLOBAL).

The *access list* and *conditional access list* comparison takes into account group membership of user IDs in the list. That is, a user ID in the conditional list of a redundant profile might be missing from the conditional access list of the candidate profile only, if one of the connect groups is present with the same access (and the same program name), and no connect groups are present with a higher access (and the same program name).

The redundancy check does not take all fields into account. For example, the RESOWNER and NOTIFY fields, security categories, levels, and labels are not checked.

For advanced users who want to provide extra selection criteria in the preamble or specify a modified query of type REPORT_REDUNDANCY or REMOVE REDUNDANT: Do not exclude profiles from the USER, GROUP, or GLOBAL classes. These classes might be needed for determining whether profiles are redundant. For example, when excluding a certain HLQ, specify EXCLUDE QUAL=*id* CLASS=DATASET!

RA.3.4 Permit/Scope - Report access of a user or group

The **RA.3.4 PERMIT/SCOPE** menu option provides an overview of all resources a user or group has access to. The access can be explicit access granted through a connect or permit, or implicit access granted through the UACC.

```
   Menu   Options   Info   Commands   Setup

```

Figure 139. Report Scope/Permit selection panel

The following selection criteria and output options are available.

Table 133. User Scope/Permit Report - selection criteria and custom output options

Selection Criteria or Output Option	Description
Id	Up to six user or group IDs for which you want this function performed
Specify type of authorization	Specify the access type you want to include in the report or display: **1** for a PERMIT to the Id, **2** for access via PERMIT or CONNECT, or **3** for access by any means.
Minimum access to show	The minimum access level for inclusion in the report
Show resources covered by each profile	Include the resource names covered by each profile.
Including data sets on scratch tapes	Include even those data sets that can be overwritten at any time because the tapes they are on are in scratch status. This option is only meaningful if you asked for inclusion of data sets in the first place.
Output in print format	Generate output in a printable format instead of in an ISPF table
Start each Id on a new page	Start each separate report on a new page. This option is only meaningful if you are generating output in print format.
Dataset HLQ	Limit the DATASET class to profiles with this HLQ as modified by `ICHCNX00` (if present), or an HLQ matching this filter.
Dataset profile	The `EGN` mask that a profile in the DATASET class must match to be included in the report.
Other class	Mask for the selection of General Resource classes
Other profile	The `EGN` mask that a profile in a General Resource class must match to be included in the report.

Figure 142. Report Permit profile display

The following information is provided on the profile level of the report.

- List of profiles
- Access level
- Access list id through which this access is granted. For conditional access, the information also reports when the access is granted

If the data sets covered by each profile are to be shown, they are listed on the detail display.

The only line commands available on this panel are **S** Select and **D** Delete.

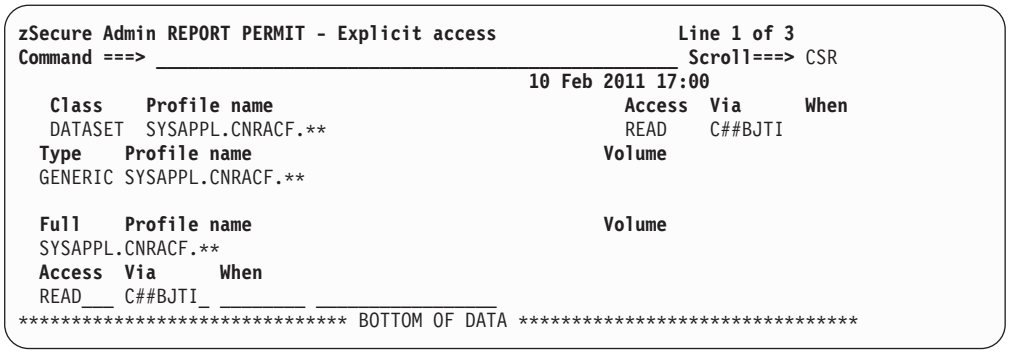

Figure 143. Report Permit detail display

The detail display shows the same information available on the record level display. However, you can also see the full profile name, up to 246 characters and modify the access allowed value.

The philosophy of the REPORT SCOPE function is to show the profiles, and optionally the resources to which the user or group *directly* or *indirectly* has access. Indirect access is the ability to modify a profile to give oneself direct access. The report includes access through the following group attributes: SPECIAL, OPERATIONS, and AUDITOR. To prevent inadvertent listing of all or almost all profiles in the system, access through the system-wide special, operations, and auditor attributes are *not* included. The report does include information about the following access types:

- Access through universal access and warning mode of profiles.
- Access through the global access table.
- Access through missing profiles.
- Access through discrete/generic DATASET profiles mismatches (in a NOPROTECTALL environment).

Because the SCOPE function includes so many different access types, it tends to produce a large quantity of output. To generate more manageable output, use the selection criteria described in Table 133 on page 208. In addition to the selection criteria, the SCOPE function also provides the follow-up panel shown in Figure 144 on page 211 with options to exclude information for selected access methods.

```
  Menu   Options   Info   Commands   Setup

```

Figure 145. Report SCOPE print format

The **Via** column shows the user ID or group in the access list entry that gave the access indicated. The value can also be any of the following:

-AUDIT-

-GLOBAL-

-RACMAP-

-RACDCT-

-SCP.G-

-SCP.ID-

-SCP.U-

- UACC -

-UNPROT-

- WARN -

- OPER -

For more information, see the “VIA” on page 1240 field description in REPORT_SCOPE NEWLIST.

The **SCP** values indicate access through the CKGRACF authorized component of Security zSecure; through a CKG.SCP.U..., CKG.SCP.G..., and CKG.SCP.ID... profile

respectively.- *AUDIT* - and - *OPER* - stand for group auditor and group operations access, respectively. In restricted mode, - *n/a* - is shown for an id that has access via the access list.

The column **Access** can show other access authorities than the conventional NONE, READ, UPDATE, CONTROL, and ALTER. These access authorities are documented with the ACCESS parameter of the REPORT command in "REPORT" on page 875.

For advanced users

If you design your own query using the REPORT_SCOPE type, you can use the SUPPRESS REASON=list command to suppress access reasons. See also "SUPPRESS" on page 932. The following reasons can be suppressed:

- *ALTER-M* to suppress accesses that would be granted because users are permitted to modify certain fields of their own user profile ('alter myself')
- *CKGOWNR* for CKGRACF-access
- *CKGRACDCERT* for access given through *IRR.DIGTCERT.** FACILITY* profiles
- *CKGRACMAP* for access given through *IRR.RACMAP.** FACILITY* profiles
- *CREATE* to suppress administrative access granted through CREATE authority on a connect and class authorization (CLAUTH) on a user.
- *GLOBAL* for global access table
- *GRPAUDIT* for propagation and consideration of group-audit authority
- *GRPOPER* for propagation and consideration of group-operations authority
- *GRPSPEC* for propagation and consideration of group-special authority
- *ID(*)* for access through the ID * on an access list
- *NOPROFILE* for unprotected data sets
- *OWNER* for owned profiles
- *PWDCHANGE* for propagation of group-special authority
- *SELFCONNECT* for propagation of group-ownership authority
- *UACC* for universal access
- *WARN* for warning mode profiles

RA.3.5 OUT OF GROUP - Group data sets that can be accessed from outside the group

The **RA.3.5 OUT OF GROUP** menu option shows permits on group data sets to users or groups outside that group. The group is taken to be the first qualifier of the dsname, optionally changed by ICHCNX00 or ICHNCV00. The report shows a group data set profiles that have a UACC other than NONE, or an OWNER or access list entry for a user outside the group or another group.

The report can be used by sites that have a simple RACF group structure with both user and data set profiles, to get a small report of profiles with a non-standard access list, as opposed to a complete list of all profiles. This is especially useful in all-discrete environments, where most of the profiles typically have a default layout.

The same selection panel as for REPORT PROFILES is used. A sample display is shown in Figure 146 on page 213.

Figure 147. Report Permits outside group detail display

The **First reason** column indicates the first reason why a profile was included in the report. There can be more reasons, but only one is spelled out. However, *all* access list entries referring outside the data set 1st-qualifier group are marked with an arrow. The reasons that can be present are:

Universal access	UACC is unequal to NONE, giving access outside the group.
User not in group	A user in the access list or OWNER field is not connected to the data set first qualifier group. If it is a user in the access list, the user is one of the entries marked with an arrow.
Other group	A group in the access list or OWNER field was present different from the data set first qualifier group. If the group is part of the access list, it is one of the entries marked with an arrow.

Note to advanced users: be careful with excluding profiles in classes other than DATASET in REPORT_OUTOFGROUP queries for reasons similar as outlined for REPORT_REDUNDANCY.

RA.3.6 Non default - Reporting nonstandard data set access lists

Use option **RA.3.6** to select all profiles that could cover the data set or resource name specified. RACF uses the most specific profile to protect a resource or data set. However, you can use this display to see what *other* profiles could also protect the resource. This can be useful to determine if the current profile is required

This report uses the same layout as the one described in the previous section.

A report of access granted outside the data set first qualifier group is not usable if your site distinguishes the grouping of data sets (resources, objects) and the grouping of users (subjects). RACF groups are used for both of these purposes. This distinction is called the concept of *data set groups*:

Data set groups are normal RACF groups, but without *any* connected user.

This contrasts with *user groups*:

User groups are normal RACF groups with users, but without *any* group data set profile (and hence, in a PROTECTALL environment, without any data sets).

The rest of the groups might be called *common groups*:

Common groups are normal RACF groups, containing *both* user profiles and group data set profiles.

Access to the data sets in a data set group is regulated by a generic profile. In this generic profile, the user group that currently owns the data sets is listed in the Access list with ALTER authority, as well as in the OWNER field. These settings provide users with group-authority in the user group so that they have control over the owned data set group. This authority is based on a connection to a user group and does not require any connections to the data set group. It also makes it a lot easier to transfer ownership of groups of data sets from one owner (a user group) to another owner (another user group). Only the ownership of the data set group needs to be changed, not all data set profiles for the data set group.

The NONDEFAULT report has been designed to support these kinds of data set profiles as *default* or *standard* in addition to those profiles containing only the data set first-level qualifier in the access list.

For group data sets, this lists 'out-of-group' access as discussed in the previous section, as well as 'out-of-group' access where the 1st qualifier is another group than the OWNER. However, user IDs in the access list are not checked for connects, but always marked as non-default, unless they are equal to either the OWNER or the 1st qualifier (an explicit PERMIT command must have been used to create this situation, and in this sense they are non-default).

In addition, user data set profiles are listed where other people than the owner are in the access list or in the OWNER field (or UACC not equal to NONE).

If your security standards differ from the standards implied here, you might prefer to see a different interpretation of the default settings and your comments on this aspect would be welcomed (direct those to the address shown on the back of the front page of this manual).

A sample report in print format is shown in the following figure.

```

```

Figure 148. Report Non-default dataset permits print format

The column **First reason** indicates why a profile was included in the report. The report only includes one reason. Although there might be more than one reason, only one is reported. However, *all* access list entries present that are considered non-default are marked with an arrow. The reasons that can be present are:

Reason	Description
Conditional access	An entry in the conditional access list is always considered non-default.
Group access	The first qualifier for the owning group or data set must be in the access list of a group data set profile to be considered default. In addition, the access must be either ALTER or UPDATE. ALTER is the preferred way, especially in a generic profile environment with PROTECTALL active, since data set creation is otherwise impossible. However, the RACF default set by the GRPACC attribute is UPDATE, therefore this is considered default, too. The entry is marked with an arrow unless it is missing from the access list.
Missing access	To be considered default, access must be granted either to the first qualifier identity or to the owner, either implicitly if the first qualifier is a user ID or explicitly through an access list entry.
More than 1 group	For an access list to be considered the default, it can contain only one group. That group must be either the first qualifier group or the owning group. Other groups are marked with an arrow.
Not owner or group	An identity in the access list is only considered default if it is the owner, or if it is a group *and* equal to the first qualifier. An undefined identity is never considered default. The identity is one of the entries marked with an arrow.
Owner access not ALTER	To be considered default, the identity owning the profile must have ALTER access to his data.
Owner not in group	The owner of a group data set profile is a user without connect to the group. **Note:** The notion of data set groups presupposes that ownership is a user group, not a user.
Universal access	UACC is unequal to NONE, giving access outside the group.

Reason	Description
User not owner	The data set name starts with a user ID. To be considered default, the data set profile owner must be that user ID.

RA.3.7 MATCH - Find profiles that cover a data set or resource

Use option **RA.3.7** to select all profiles that could cover the data set or resource name specified. RACF uses the most specific profile to protect a resource or data set. However, you can use this display to see what *other* profiles could also protect the resource. This can be useful to determine if the current profile is required.

```

Figure 151. Profile match detail display

The fields on the display panels are like the fields on a normal DATASET or RESOURCE display panel. However, the default sort order, the positioning of certain fields, and the amount of information included are different.

RA.3.8 GROUP TREE - Group tree display

Option **RA.3.8** provides an overview of the group structure of the system in a tree format. When you select this option, the Reports Group tree panel opens so you can specify selection criteria to select or exclude parts of the group structure.

```
   Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                          zSecure Suite - RACF - Reports Group tree
Command ===>                                                  _ start panel

Show structured group tree display:
Group id  . . . . . ________     (group profile key or filter)
Start at  . . . . . C##QA*__     (group or filter, show only groups below)
Scope of  . . . . . ________     (group special, show only groups in scope)
Exclude . . . . . . ________     (group or filter)
Complex . . . . . . ________     (complex name or filter)

Enter "/" to include data in output
 /  Installation data
 /  Users/Subgroups

Enter "/" to select option
_  Output in print format

'Start at' is only permitted with an unload as data source, not a live database
```

Figure 152. Report Group tree selection panel

The following selection criteria are supported:

Table 135. Group Tree Display - selection criteria

Selection criteria	Description
Group id	Group name or filter. Only matching groups are displayed
Start at	Only groups in the subtree with this group at the top is displayed. This type of selection is only supported for an UNLOAD.
Scope of	Show only groups in the scope of this user ID (meant for group special users)
Exclude	Group name or filter. Matching groups are not displayed
Complex	Name of complex name to show group tree for, or filter

In addition, the installation data of the groups shown can be included if desired, and (in display format only) the users connected to the groups, and the groups' subgroups can be shown on a detail display.

A sample group tree display is shown in the following figure.

```

Command ===>

Specify selection criteria for USERDATA:
Class . . . . . ________
Profile . . . . . ________________________________________________________________
Complex . . . . . ________

Entry name  . . . . PHONE_____
Entry flag  . . . . __   (hexadecimal number, no filter)
Entry value . . . .
010*_____________________________________________________________________________

All fields but you can use the Entry flag field for either an exact match or a filter.
```

Figure 155. USERDATA selection panel

In the preceding example, we query for PHONE entries of which the contents starts with `010`.

The following selection criteria are supported.

Table 137. USERDATA - selection criteria

Field	Description
Class	The profile class, or filter.
Profile	The profile name, or filter.
Complex	The complex name, or filter.
Entry name	The name of the USERDATA entry, or a filter.
Entry flag	The USERDATA flag byte (hex).
Entry value	The value of the USERDATA entry, or filter.

This panel is not the intended interface to work with CKGRACF USERDATA entries. Therefore, entry names that start with *CKG* are suppressed unless you explicitly specify an **Entry name** starting with *CKG*.

The result of a query is a panel as shown in the following figure.

```
zSecure Admin Display Selection                  1 s elapsed, 0.3 s CPU
Command ===> ____________________________________________________ Scroll===> CSR

  Name     Summary Records Title
_ USERS          2       2 USERDATA values in user profiles

****************************** BOTTOM OF DATA ********************************
```

Figure 157. USERDATA profile display

The other displays are similar in layout, but show the profile name under **Group** or **Profile key** instead of **User**, and have no **Name** field.

The following fields of interest are shown.

Table 138. USERDATA detail display

Field	Description
User	The profile name
Name	For users the programmer name
EntryNam	The USERDATA entry name
Fl	The USERDATA flag byte (hex)
Value	The USERDATA entry value

If there is only one (selected) USERDATA entry, it is shown on the profile display. If there are several entries, the listing shows the value <*more*>. The additional values are listed on the detail display panel. You can start the USERDATA management functions on the profile display with the **MU** line command. However, when you use this method, no entry information is passed to the command, and you have to enter the information manually. Therefore, for most management functions, it is easier to use the detail display.

A detail display is shown in the following figure.

```
USERDATA values in user
Command ===>                                                Scroll===> CSR

****************************** BOTTOM OF DATA ********************************
```

Figure 158. USERDATA values in user panel - detail display

The **D** Delete line command displays the following panel. You can optionally specify a reason when deleting an entry which consists of the name and value pair. For the **D** command, **Reason** is the only modifiable field.

```
                        Security zSecure - Delete USERDATA
Option ===>

Class . . . . . . . . USER____
Profile . . . . . . . 'ibmuser'c_____________________
Entry name  . . . . . PHONE___
Entry flag  . . . . . 00
Entry value . . . . . 0107823_____________________________________________________
_____________________________________________________________________________
_____________________________________________________________________________
_____________________________________
Reason
_____________________________________________________________________________
```

Figure 159. Delete USERDATA panel

The **R** Recreate line command creates another copy of the entry. The recreate option can be used to add another entry only if the command confirmation setting is turned on.

The **I** Insert, **C** Copy, and **S** Modify line commands bring up a panel to manage the `userdata`. The **C** and **S** commands result in a panel that provides all the values from the `userdata` entry. For the **I** command, only the Class and Profile data from the entry is included on the panel.

```
                        Security zSecure - Add USERDATA
Option ===>

Class . . . . . . . . USER____
Profile . . . . . . . 'ibmuser'c_____________________

```

Figure 160. Add USERDATA panel

At the top the class and name of the profile you are working with is shown.

RA.3.A TAPEVOL - Tape Profile Overview

Option **RA.3.A** opens the Reports Tapevol panel, a variant of the General Resource Profiles panel that applies to the TAPEVOL class.

```
   Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                         zSecure Suite - RACF - Reports Tapevol
Command ===>                                                  _ start panel

Show tape profiles that fit all of the following criteria:
Volume  . . . . . . ________     (tape volser or filter)
Owned by  . . . . . ________     (group or userid, or filter)
Complex . . . . . . ________     (complex name or filter)

 / Specify more selection criteria and output options

Display options used (change with "Setup View" or "Setup Confirm"):
user/grp info Y, action commands EXECUTE, confirm level ALL
```

Figure 161. TAPEVOL simple query panel

The simple query panel is shown in the preceding figure. The advanced selection panel is shown in the following figure.

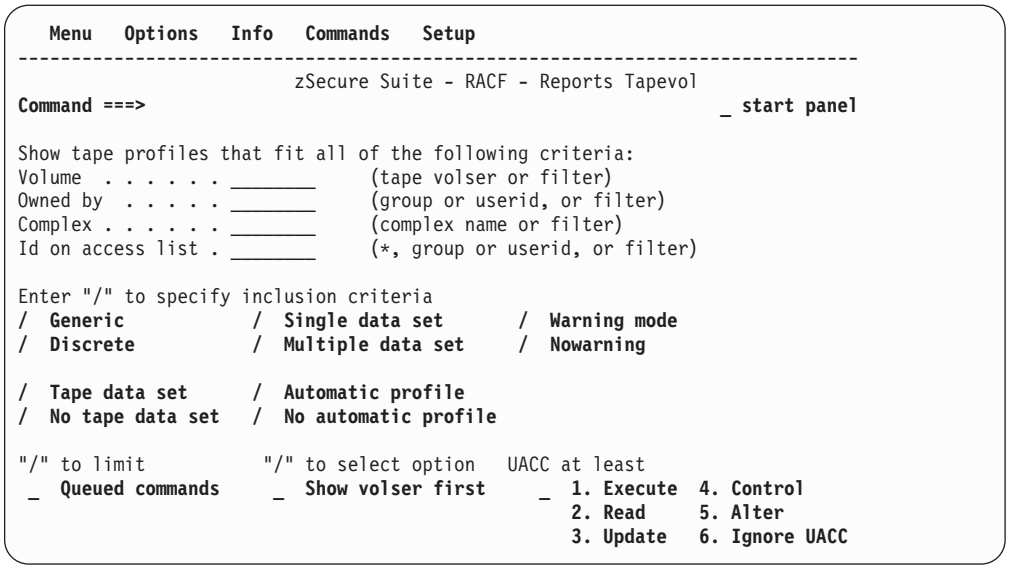

Figure 162. TAPEVOL advanced selection panel

The **Enter "/" to specify inclusion criteria** contains option pairs that are checked by default: Both generic and discrete profiles are shown based on the selection criteria specified on the Reports Tapevol panel. If you select options in the **"/" to limit** group, the selection is limited to only those profiles that possess the characteristics selected.

The following selection criteria are supported.

Table 139. Tapevol report - selection criteria

Selection criteria	Description
Volume	Tape volume occurring in the profile key or in the volume list.
Owned by	Profiles owned by the user or group you specified.
Complex	In a complex with this name, or a matching complex if a filter is used.
Id on access list	User or group on the access list (access that a user has through a group is *not* supported in this selection)
Generic	Show generic profiles.
Discrete	Show discrete profiles.
Single data set	Show profiles with single data set attribute.
Multiple data set	Show profiles without the single data set attribute.
Warning mode	Show profiles in Warning mode.
No Warning	Show profiles not in Warning mode.
Tape data set	Show profiles with tape data sets.
No tape data set	Show profiles without tape data sets.
Automatic profile	Show profiles with automatic attribute.
No automatic profile	Show profiles without the automatic attribute.
Queued commands	Show only groups that have one or more commands in the command queue.
UACC at least	Show any UACC that grants access greater than or equal to the specified value.

If you select the output option **Show volser first**, an overview of all volume serial names is presented first. Then, the profile data is listed per volume serial. If you do not select this option, the volume serial overview is not included.

A sample TAPEVOL profile display is shown in the following figure.

```

Enter "/" to specify output option(s)
_  Show member names
_  View by duplicate entries
_  Sort member list
_  Show profiles that use Variable name
_  Output in print format
```

Figure 166. RACFVARS advanced selection panel

The following selection criteria are supported.

Selection criteria	Description
Variable name	Variable name matching the pattern.
Member values	Text strings that can appear anywhere in the member name. A pattern match is not supported (instead, a *substring scan* is always performed). If a list of values is specified, profiles are selected that contain any of the specified member names.
Owned by	Lists the OWNER you specified. The owner can be a user or group.
Complex	In a complex with this name, or a matching complex if a filter is used.
Id on access list	User or group on the access list (access that a user has through a group is *not* supported in this selection).

The following output options are available.

Table 141. RACF Variable Profile report - output options

Output option	Description
Show member names	Generate a display showing member names first, and show profiles that contain this member second.
View by duplicate entries	Generate a display showing only member names that appear in more than one RACFVARS profile.
Sort member list	Sort the member list. RACF determines matches by the *unsorted* member list, but always displays a sorted member list.
Show profiles that use Variable name	Include an extra display with profiles referring to a specific Variable name (requires the Variable name field to be filled in).
Output in print format	Generate output in printable format instead of in an ISPF table.

A sample RACFVARS overview panel is shown in the following figure.

```

Figure 173. SDSF profile display

On the detail display for SDSF, GSDSF and OPERCMDS the ACL entries are shown. For GSDSF and GLOBAL the member list is shown.

This option is a variant of **RA.R**, so see "RA.R RESOURCE - General Resource profiles" on page 147 for the available line commands.

RA.3.F JES2 - Access to JES2 resources

Option **RA.3.F** generates an overview of profiles that affect JES2 security. Use the selection panel to specify whether you want the output in print format rather than as an ISPF table.

A sample display is shown in the following figure.

```
zSecure Admin Display Selection                 1 s elapsed, 0.5 s CPU
Command ===>                                              Scroll===> CS

  Name     Summary Records Title
_ GLOBAL         2       2 zSecure Admin JES control profiles
_ JESINPUT       3       3 zSecure Admin JES input sources for job submis
_ FACILITY       2       2 zSecure Admin JES RACF validation of /*SIGNON
_ JESJOBS        1       1 zSecure Admin JES submit and cancel control
_ JESSPOOL      43      43 zSecure Admin JES sysin/sysout dataset access
_ NODES         12      12 zSecure Admin JES validation of inbound data c
_ WRITER         1       1 zSecure Admin JES outbound data control
_ PROPCNTL       0       0 zSecure Admin JES userid propagation control
_ SURROGAT      45      45 zSecure Admin JES surrogate submit control
****************************** BOTTOM OF DATA *******************************
```

Figure 174. JES2 resources overview display

Resources from these classes are shown:

Table 144. Display selection - class resources

Resource	Description
GLOBAL	Global access checking for JES control profiles
JESINPUT	JES input sources for job submission control
FACILITY	JES RACF validation of /*SIGNON and SNA LOGON
JESJOBS	JES submit and cancel control
JESSPOOL	JES sysin/sysout dataset access control
NODES	JES validation of inbound data control
WRITER	JES outbound data control
PROPCNTL	JES userid propagation control
SURROGAT	JES surrogate submit control

This option is a variant of **RA.R**.

RA.3.G Compare users - Compare access and/or connect

Use this option to do the following comparisons:

- Compare access through permits with an option to include group permits.
- Compare connects for up to four userids

When you select RA.3.G, the following panel opens:

```
   Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                          zSecure Suite - RACF - Reports - Compare
Command ===> ____________________________________________________________________

Enter up to 4 userids to compare access and/or connects
Userid  . . . . SECADM1_     SECADM2_     ________     ________

Select report(s)
_  Compare access through user-specific permits
   _  Include group permits
_  Compare connects
```

Figure 175. Compare selection panel

Table 145 lists the available selection criteria and output options

Table 145. Compare selection - selection criteria

Selection criteria	Description
Userid	Enter up to 4 user IDs to compare. Masks are not permitted.
Compare access through user-specific permits	Compare access through an explicit permit for the user IDs entered.
Include group permits	This option is only effective when **Compare access through user-specific permits** is selected as well. The generated report also displays access through group connects.
Compare connects	Compare the group connects for the user IDs entered.

Figure 176 shows the panel that is displayed when all options are selected:

```
zSecure Suite Display Selection                                  Line 1 of 2

RA.4 MASS UPDATE - Specify mass copy/recreate/delete actions

The MASS UPDATE application provides an easy way to change, add, or delete multiple profiles in one run. The functions provided are the same as the functions available from the corresponding line commands. However, the MASS UPDATE update function permits you to run these commands on multiple profiles.

The MASS UPDATE application is an advanced function for experienced security administrators who understand the impact of their selections and actions.

```
  Menu   Options   Info   Commands   Setup   StartPanel
------------------------------------------------------------------------------
                        zSecure Suite - RACF - Mass update
Option  ===> ____________________________________________

0    Copy user       Copy existing user(s) to new user(s)
1    Copy group      Copy existing group(s) to new group(s)
2    Copy dataset    Copy dataset profile(s) to another high level qualifier
3    Copy resource   Copy general resource profile(s) to another class
4    Delete user     Delete user(s)
5    Delete group    Delete group(s)
6    Recreate user   Recreate user(s)
7    Recreate grp    Recreate group(s)
8    Recreate ds     Recreate dataset profile(s)
9    Recreate res    Recreate general resource profile(s)
C    Copy CICS       Copy CICS prefixed profile(s) or member(s)
```

Figure 182. Mass update menu

Use the COPY options to specify several profiles of the selected type that must be created like an existing profile. Copying is also called *cloning*.

Use the DELETE options to perform daily maintenance functions for the user entry staff. These options generate commands to delete user or group profiles and all references to the IDs from the RACF database. Specify commas before a value if you also want to remove all the data sets covered by the removed profiles, including cataloged data sets migrated (volume `MIGRAT` or `ARCIVE`) to tape, but excluding migrated-but-uncataloged and true tape data sets. If you do not supply a `CKFREEZE` file, resource deletion is automatically skipped. For information on the REMOVE command, see "REMOVE" on page 870.

The RECREATE options are designed to generate commands from a RACF database that can be used for rebuilding selected profiles as they exist in that database. For example, you can use the RECREATE option after a profile has been inadvertently deleted. To reinstate the profile, restore the RACF database form last week, and then define an input set containing these data sets as described in “SE SETUP - Options and input data sets used” on page 1641. You can then run any report against the old database, and use RECREATE to generate RACF commands for the profiles you lost.

You can also use RECREATE to generate RACF commands that you manipulate with the editor to create a COPY routine.

RA.4.0 Copy user - Copy an existing user to a new user

Use option **RA.4.0** to create, or clone several user profiles from one or more model user profiles at the same time. Figure 183 shows the User Multiple copy panel for performing these tasks.

```
  Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                         zSecure Suite - RACF - User Multiple copy
Command ===>

Create new user(s) like existing user(s):
_  Specify password phrases

Model    New
User     User     Password Name                 Owner    Dfltgrp  Data
c##bjti_ c##bjt3_ JJW_____ JOYCE_TIMBERLINE____ c##bjti_ c##b____ _________
=_______ c##bjt4_ =_______ =____________________ =_______ =_______ _________
c##bjt2_ c##bjt5_ =_______ =____________________ =_______ =_______ _________
________ ________ ________ ____________________ ________ ________ _________
________ ________ ________ ____________________ ________ ________ _________
________ ________ ________ ____________________ ________ ________ _________
________ ________ ________ ____________________ ________ ________ _________
________ ________ ________ ____________________ ________ ________ _________
________ ________ ________ ____________________ ________ ________ _________
________ ________ ________ ____________________ ________ ________ _________

Enter = to copy value from preceding line, leave blank to copy from model.

Press ENTER to specify optional parameters.
```

Figure 183. User Multiple copy panel

On each line, specify the existing user that provides the model to copy from, the new user to create, and any characteristics that are not to be copied from the model user. In the following lines, you can specify = to use the same value used on the preceding line.

If the new user must be a protected user ID, enter * as password.

If you select **Specify password phrases**, a follow-up panel is shown for setting password phrases for the new user IDs. This option cannot be combined with entering a * (for protected) for all new users.

When you press **ENTER** on the User Multiple copy panel, the = markers are replaced by repetitions from the preceding lines, as shown in Figure 184 on page 235.

```
 Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                zSecure Suite - RACF -          Default prompting
Command ===>

Create new user(s) like existing user(s):
_  Specify password phrases
Model    New
User     User     Password Name                 Owner    Dfltgrp  Data
C##BJTI_ C##BJT3_ JJW_____ JOYCE_TIMBERLINE____ C##BJTI_ C##B____ ______
C##BJTI_ C##BJT4_ JJW_____ JOYCE_TIMBERLINE____ C##BJTI_ C##B____ ______
C##BJT2_ C##BJT5_ JJW_____ JOYCE_TIMBERLINE____ C##BJTI_ C##B____ ______
________ ________ ________ ____________________ ________ ________ ______
________ ________ ________ ____________________ ________ ________ ______
________ ________ ________ ____________________ ________ ________ ______
________ ________ ________ ____________________ ________ ________ ______
________ ________ ________ ____________________ ________ ________ ______
________ ________ ________ ____________________ ________ ________ ______
________ ________ ________ ____________________ ________ ________ ______

Enter = to copy value from preceding line, leave blank to copy from model.

Press ENTER to specify optional parameters.
```

Figure 184. User Multiple copy panel - user selection

When you press **Enter** again, the panel shown in Figure 185 opens.

```
 Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                      zSecure Suite - RACF - User Multiple copy
Command ===> ____________________________________________________________

Optional parameters
Do not connect new user(s) to following group(s):
________  ________  ________  ________  ________
________  ________  ________  ________  ________
Also connect new user(s) to following group(s):
________  ________  ________  ________  ________
________  ________  ________  ________  ________

 _  Generate RACF commands even when the target user exists
 _  Copy USERDATA and CUSTOMDATA

Specify options for new userid
_  Revoke new userid
/  Copy catalog aliases (only if CKFREEZE is present)
_  Issue ADDSD/RDEF for dataset and resource profiles related to the user
   /  Copy RACFVARS profiles/members too

Press ENTER to generate TSO and RACF commands.
```

Figure 185. User Multiple copy panel

Optionally, you can specify groups that users cannot connect to even though the model user is connected. You can also specify groups that the user can connect to. Selecting the **Generate RACF commands** option when the target user exists forces the program to generate commands even though the user exists.

When you select **Copy USERDATA and CUSTOMDATA**, CKGRACF commands are generated to copy the user data. RACF commands are also generated to copy custom fields. You can also specify the following options:

- Make new users revoked initially to prevent default passwords from being available.

- Whether to clone catalog aliases.
- Whether to clone user-specific data sets and general resource profiles like STARTED and SURROGAT profiles.

  If they are cloned, you can indicate whether the RACFVARS profiles also require cloning.

Note: By default, the occurrence of a valid user ID as a member or the key of a RACFVARS profile is considered meaningful, although RACF itself assigns no special meaning to this occurrence..

After specifying all the criteria, press **Enter** to generate the applicable RACF and TSO commands. The results are shown in an edit panel showing the CKRCMD file.

RA.4.1 Copy group - Copy existing groups to new groups

Use option **RA.4.1** Copy group to create (or *clone*) several groups from one group at the same time. The panel presented for this purpose is shown in the following figure.

```
 Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                          zSecure Suite - RACF - Mass update - Copy group
Command ===> ____________________________________________________________

From group  . . . . ________
To id . . . . . . . ________ ________ ________ ________ ________
                    ________ ________ ________ ________ ________

_  Copy permits only (target id may be a group or a user)
_  Generate RACF commands even when the target group exists
_  Copy CUSTOMDATA

Specify options for new group:
_  Copy catalog aliases (only if CKFREEZE is present)
_  Issue ADDSD/RDEF for user resources
  _  Copy RACFVARS profiles/members too (if option above selected)
```

Figure 186. Group multiple copy panel

Optionally, you can suppress the error message indicating that the new group ID exists. The suppress command effectively adds connections and permits of the model group to the target groups. By selecting **Copy permits only**, you indicate that the permits of the model group are to be added to the target groups or users. No CONNECT or ADDGROUP commands are generated.

When the **Copy CUSTOMDATA** option is selected, RACF commands are generated to copy custom fields. You can also specify whether catalog aliases are to be cloned and whether group-specific data sets and general resource profiles are to be cloned as well. If these profiles are cloned, then you can also specify whether the RACFVARS profiles are also to be cloned.

Note: By default the occurrence of a valid group ID as a member or the key of a RACFVARS profile is considered meaningful, although RACF itself assigns no special meaning to this occurrence.

After completing this panel, press **Enter** to generate the applicable RACF and TSO commands. The generated commands are shown in an edit panel showing the CKRCMD file.

RA.4.2 Copy dataset - Copy dataset profiles to another High-level qualifier

Use option **RA.4.2** Copy dataset to copy DATASET profiles with a specific High-level qualifier to another HLQ.

```
   Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                          zSecure Suite - RACF - Data set Multi-Copy
Command ===>

Copy dataset profiles that match the following high qualifier:

Dataset HLQ . . . . C##BJTI_

To qualifier  . . . C##BJT3_

This function is not available in restricted mode
```

Figure 187. Dataset multiple copy panel

In this panel you specify the **Dataset HLQ** for which profiles are to be copied, and the qualifier they are to be copied to. This destination qualifier is not verified to see if it is a valid user or group, even though the generated commands fail if the user or group is not valid.

This might result in output as shown in the following figure.

```
EDIT       C##BJTI.C2R1EF2A.CKRCMD                        Columns 00001 00072
Command ===>                                                 Scroll ===> CSR
Press PF3, enter R at the cursor location, press ENTER to run these commands
000001         /* CKRCMD file CKR1CMD complex DINO NJE JES2DINO generated  3 No
000002          /* Commands generated by COPY PERMIT       */

000004         addsd 'C##BJT3.RE.DUN.DANT.**' generic from('C##BJTI.RE.DUN.DANT
000005         altdsd 'C##BJT3.**' generic owner(C##BJT3 )
000006         altdsd 'C##BJT3.RE.DUN.DANT.**' generic owner(C##BJT3 )
000007         SETROPTS REFRESH GENERIC(DATASET)
****** ***************************** Bottom of Data ****************************
```

Figure 188. Dataset multiple copy commands

After reviewing the commands, and altering them as desired, PF3 exits the panel and returns you to the RESULTS panel where you can specify **R** Run in front of the CKRCMD file to run the commands.

RA.4.3 Copy resource - Copy general resource profiles to another class

Use option **RA.4.3 Copy resource** to copy general resource profiles (matching a pattern) from one class to another. Make sure to specify an existing class as the destination because the program does not check the class value. If you specify an invalid class, the generated commands fail when they are run.

```
 Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - RACF - Resource Multi-Copy
Command ===>

Copy general profiles that fit all of the following criteria:
Class name  . . . . GCICSTRN     (class or filter)
Profile pattern . . **_____________________________________________ (EGN mask)

To class  . . . . . GCIC2TRN
```

Figure 189. Resource multiple copy panel

In the preceding example, all profiles in the GCICSTRN class are copied to class GCIC2TRN.

RA.4.4 Delete user - Delete users

Use option **RA.4.4 Delete user** to delete or remove user IDs, connections, and permissions. Depending on the options you select, you can generate the following types of delete and remove commands which you can edit and submit for processing:

- Delete multiple user IDs.
- Move these user IDs to a different holding group.
- Remove only permits.
- Remove users from the NOTIFY fields.

You can generate the commands to process up to 12 user IDs at one time.

```
    Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                           zSecure Suite - RACF - User Delete
Command ===>

Userid  . . . . . . ________ ________ ________ ________ _______ ________
                    ________ ________ ________ ________ _______ ________
Specify action to perform
_  1. Delete userid
   2. Move userid to holding group ________
   3. Remove userid from resource profiles (remove permit)
   4. Remove userid from NOTIFY fields

Specify resources to delete (actions 1, 2 and 3 only)
/  Data set and id-specific profiles
   Only if previous option selected:
   _  RACFVARS profiles and members
   /  Data sets and their catalog entries
      /  Incl. catalog entries without data sets
      /  Incl. uncataloged data sets

Change USERID in Notify fields to   ________  (default is NONOTIFY)
New Owner for non-dataset profiles  SYS1____  (default is SYS1)
```

Figure 190. User multiple delete panel

Enter the user IDs to be processed in the **Userid** field. Then, choose the action to be performed.

1 Delete userid. Deletes the user ID and all references and profiles solely in use for that user. This action generates the following command: REMOVE USER=*id*. command. refer to “REMOVE” on page 870.

2 Move userid to a holding group. Revokes the user ID, deletes the user ID current connections, and connects it to the specified holding group. This action generates the following command: REMOVE USER=*id* TOGROUP=*group* REVOKE.

3 Remove userid from resource profiles Removes the user ID from the resource profile without deleting the user ID connections or the profile itself. This action generates the following command: REMOVE NOTIFY=*id*.(REMOVE PERMIT=*id*).

4 Remove userid from NOTIFY fields Only deletes the user ID from NOTIFY fields. This action generates the following command: REMOVE NOTIFY=*id*.

The options control to what extent delete commands are generated:

Dataset and id-specific profiles
Deletes ID-specific profiles. If this option is not selected, the removal of user-specific profiles is suppressed, and data sets are kept. Deleting a user ID fails if the user ID is associated with any of the remaining data set profiles.

RACFVARS profiles and members

Security zSecure expects that the occurrence of a valid user ID as a key preceded by an ampersand (*&userid*) or a member of a RACFVARS profile to be meaningful. As a result, if you select the option, the profile or profile member is removed accordingly.

Datasets and their catalog entries
When you select this option and a CKFREEZE file has been allocated, the deletion of profiles is preceded by the deletion of the data sets covered by them. This means that unprotected or inaccessible data sets with an HLQ that matches the removed ID are also removed.

This option also deletes catalog entries based on the following option settings:

- If **Incl. Catalog entries without datasets** is selected, the entries deleted depend on the DELETE NOSCRATCH option setting when necessary.
- If **Incl. Uncataloged data sets** is selected, uncataloged non-VSAM data sets from the VTOC are scratched.

See “SUPPRESS” on page 932 for more information about the effect of delete operations when volumes or catalogs are explicitly excluded, or when they are implicitly excluded by not supplying enough `CKFREEZE` files for the analysis as can happen with partially shared DASD, . Resource deletion commands are explicitly targeted at the current system. If you must run additional resource deletion commands from another system, do not forget to update your `CKFREEZE` files.

You can also specify a replacement for the occurrence of the user in `NOTIFY` and `OWNER` fields. The default behavior is to delete NOTIFYs and replace `OWNER`s by *SYS1*.

RA.4.5 Delete group - Delete groups

Use option **RA.4.5 Delete group** to generate the commands to delete multiple groups or to only remove the permits. You can generate the commands to process up to 12 user IDs at one time.

Resource deletion commands are explicitly targeted at the current system. If you need to run additional resource deletion commands from another one, do not forget to update your CKFREEZE files.

```
   Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                          zSecure Suite - RACF - Group Delete
Command ===>

Group . . . . . . . ________ ________ ________ ________ ________ ________
                    ________ ________ ________ ________ ________ ________

Specify action to perform
 _  1. Delete group
    2. Remove group from resource profiles (remove permit)

Options for delete group                          Options for connected users
Enter "/" to select option(s)                     Delete all USERs ...
 /  Dataset and id-specific profiles                /  owned by GROUP
    Only if previous is selected:                   _  connected to GROUP
    _  RACFVARS profiles and members                _  with defaultgrp GROUP
    /  Data sets and their catalog entries         Or move USERs to holding
       /  Incl. catalog entries without data sets            group ________
       /  Incl. uncataloged data sets

Change USERID in Notify fields to   NONOTIFY  (default is NONOTIFY)
New Owner for non-dataset profiles  SYS1____  (default is SYS1)
```

Figure 191. Group multiple delete panel

Enter the groups to be processed in the **Group** field, and choose the action to be performed.

1 Delete groupid. Deletes the group ID and all references and profiles solely in use for that group. This action generates the following command: `REMOVE GROUP=id`.

2 Remove groupid from resource profiles Deletes the group permissions without deleting the group. This action generates the following command: `REMOVE PERMIT=id`.

For information on the REMOVE commands, see "REMOVE" on page 870.

The options control to what extent delete commands are generated:

Dataset and id-specific profiles
Deletes ID-specific profiles. If this option is not selected, the removal of group-specific profiles is suppressed, and data sets are kept. Deleting a group ID fails if the group ID is associated with any of the remaining data set profiles.

RACFVARS profiles and members

Security zSecure expects that the occurrence of a valid group ID as a key preceded by an ampersand (*&groupid*) or a member of a RACFVARS profile to be meaningful. As a result, if you select the option, the profile or profile member is removed accordingly.

Datasets and their catalog entries
When you select this option and a `CKFREEZE` file has been allocated, the deletion of profiles is preceded by the deletion of the data sets covered by them. This processing behavior means that unprotected or inaccessible data sets with an HLQ that matches the removed ID are also removed.

This option also deletes catalog entries based on the following option settings:

- If **Incl. Catalog entries without datasets** is selected, the entries deleted depend on the DELETE NOSCRATCH option setting when necessary.
- If **Incl. Uncataloged data sets** is selected, uncataloged non-VSAM data sets from the VTOC are scratched.

See “SUPPRESS” on page 932 for more information about the effect of delete operations when volumes or catalogs are explicitly excluded, or when they are implicitly excluded by not supplying enough CKFREEZE files for the analysis as can happen with partially shared DASD. Resource deletion commands are explicitly targeted at the current system. If you must run additional resource deletion commands from another system, do not forget to update your CKFREEZE files.

A simple group deletion only works if the group does not contain any users. For that reason the panel offers the options to delete users owned by the group, connected to the group, or having the group as default group. You also have the option to remove the users from the group by revoking the user IDs and moving them to a holding group.

You can also specify a replacement for the occurrence of the group in NOTIFY and OWNER fields. The default behavior is to delete NOTIFY statements and replace OWNERs values with *SYS1*.

RA.4.6 Recreate user - Recreate users

Use the Recreate user option (**RA.4.6**) to generate commands to recreate one or more user IDs.

You can also edit the generated commands to copy the user ID instead of recreating it. This type of copy is useful if you already have permits for users like ADGRANT, ADGRANT1 and want to add permits for COPGRANT, COPGRAN1.

Although you can use an UNLOAD file as the input for the RECREATE USER command, the recreated profile can be incomplete or wrong because the user information in the UNLOAD file is not current. Also, in the UNLOAD file all sensitive fields like password and password phrase are always created with a mask ********.

```
  Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - RACF - User Recreate
 Command ===>

Recreate userid . . ________     (user profile key or filter)
Owner . . . . . . . ________     (group or userid, or filter)

Specify options for recreate
/  Copy Dataset and General Resource profiles for this user
/  Copy Access List entries with this user
/  Use CKGRACF to update the user profile
```

Figure 192. User Recreate panel

.

The following selection criteria are available.

Table 146. Recreate user - selection criteria

Selection criteria	Description
Recreate userid	The user ID to be recreated, or a filter
Owner	The owner of the user IDs to be recreated, or a filter

If you want the user IDs DATASET and General Resource profiles to be recreated as well, select the **Copy Dataset and General Resource profiles for this user**

recreate option. If you want the user ID to be reinstated with PERMITs on profile access lists, select **Copy Access List entries with this user**. If you select this option, you can also select the **Use CKGRACF to update the user profile** setting to generate the CKGRACF commands to restore additional information, USERDATA and CKGRACF data for example.

The user that is running the generated CKGRACF commands must have sufficient access for running these commands, and the users to be defined must be in the user's CKGRACF scope. The use of the CKGRACF FIELD command is not subject to scope checks. See "CKGRACF authority checks" on page 1559.

RA.4.7 Recreate grp - Recreate groups

User option **RA.4.7 Recreate group** to generate commands to recreate one or more groups.

You can also edit the generated commands to copy the group ID instead of recreating it. This type of copy is useful if you already have permits for groups like *SYS1R*, *SYS1U* and want to add permits for SYS9R, SYS9U

RECREATE can also be used to copy profiles. After you run the command, you can edit the resulting commands to specify the name of the profile to copy to. This operation can be an effective copy method if you already have permits for groups and want to add permits for SYS9R, SYS9U, and so on.

```
  Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - RACF - Group Recreate
 Command ===>

Recreate groupid  . ________     (group profile key or filter)
Owner . . . . . . . ________     (group or userid or filter)

Specify options for recreate
_  Copy Dataset and General Resource profiles for this group
/  Copy Access List entries with this group /  Use CKGRACF to update the group profile
```

Figure 193. Group recreate panel

The following selection criteria are available.

Table 147. Recreate group - selection criteria

Selection criteria	Description
Recreate groupid	The group to be recreated, or a filter
Owner	The owner of the groups to be recreated, or a filter

If you want the DATASET and General Resource profiles for the group to be recreated as well, select the first option. If you want the group to be reinstated with PERMIT statements on profile access lists, select the second option. Select the third option to generate CKGRACF commands to restore additional information like USERDATA and CKGRACF data.

RA.4.8 Recreate ds- Recreate data set profiles

Option **RA.4.8 Recreate dataset** can be used to generate commands to recreate one or more data set profiles.

```
 Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - RACF - Data set Recreate
Command ===>

Profile pattern . . _____________________________________________ / EGN mask
Qualifier . . . . . ________     (or filter as modified by ICHCNX00)
Owner . . . . . . . ________     (group or userid or filter)

Specify options for recreate
```

Figure 194. Data set Recreate panel

The following selection criteria are supported.

Table 148. Recreate data set profile - selection criteria

Selection criteria	Description
Profile pattern	The *name* of the profile to be recreated if the **EGN mask** option is unchecked, otherwise a *filter*
EGN mask	Whether to interpret the profile patterns specified as a filter rather than a name
Qualifier	The High-level qualifier of the profile (as modified by ICHCNX00 if present), or a filter
Owner	The owner of the profiles to be recreated, or a filter

Select the **Use CKGRACF** option to generate CKGRACF commands to restore additional information like USERDATA and CKGRACF data.

RA.4.9 Recreate res - Recreate general resource profiles

Option **RA.4.9 Recreate resource** can be used to generate commands to recreate one or more general resource profiles.

Although you can use an UNLOAD file as the data source for RECREATE operations, doing so can result in incorrect information because any masked or confidential fields included in the data are not recreated properly.

```
 Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - RACF - Resource Recreate
Command ===> _____________________________________________________________

Profile pattern . . ____________________________________________ / (EGN mask)
Owner . . . . . .   ________
Search  . . . . .   ____________________________________________________________
____________________________________________________________________________

Specify options for recreate
/  Use CKGRACF to update the general resource profile
```

Figure 195. Resource Recreate panel

The following selection criteria are available.

Table 149. Recreate general resource profiles - selection criteria

Selection criteria	Description
Recreate class	The class to recreate profiles from, or a filter

Table 149. Recreate general resource profiles - selection criteria (continued)

Selection criteria	Description
Profile pattern	The *name* of the profile to be recreated if the **EGN mask** option is unchecked, otherwise a *filter*
EGN mask	Whether to interpret the profile patterns specified as a filter rather than a name
Owner	The owner of the profiles to be recreated, or a filter
Search	Text strings to search for anywhere in the profile

Select the **Use CKGRACF** option to also generate `CKGRACF` commands to restore additional information, `USERDATA` and `CKGRACF` data for example.

Currently, the classes UNIXMAP, DIGTNMAP, DIGTCERT and DIGTRING are not supported here.

RA.4.C Copy CICS - Copy CICS prefixed profiles or members

You can use Option **RA.4.C** Copy CICS for copying CICS prefixed profiles, or CICS prefixed members of grouping classes. The panel presented for this purpose is shown in the following figure.

```
 Menu  Options  Info  Commands  Setup
--------------------------------------------------------------------------------
                        zSecure Suite - RACF - Copy CICS
Command ===> ____________________________________________________________

Class  . . . . . . . _________  (CICS resource class)
Profile pattern  . . ____________________________________________  (EGN MASK)
From CICS prefix . . _________  (Source CICS userid when grouping class)

To CICS prefix . . . _________  (CICS userid for prefixing new profile(s))
```

Figure 196. Copy CICS prefixed profiles panel

The following selection criteria are supported.

Table 150. CICS profiles, members, or grouping classes - selection criteria

Selection criteria	Description
Class	The CICS resource class, or a filter. This field is a required input field.
Profile pattern	The CICS profile name, or a filter. This field is a required input field.
From CICS prefix	The CICS source `userid`. This value is the profile High-level qualifier, or member prefix for grouping classes.
To CICS prefix	The target CICS `userid`. Commands are generated to add a new profile that uses this ID as the High-level qualifier, or add members to the CICS profiles for grouping classes.

RA.5 DIGTCERT - Work with digital certificates

The menu option RA.5 (DIGTCERT) can be used to select digital certificates.

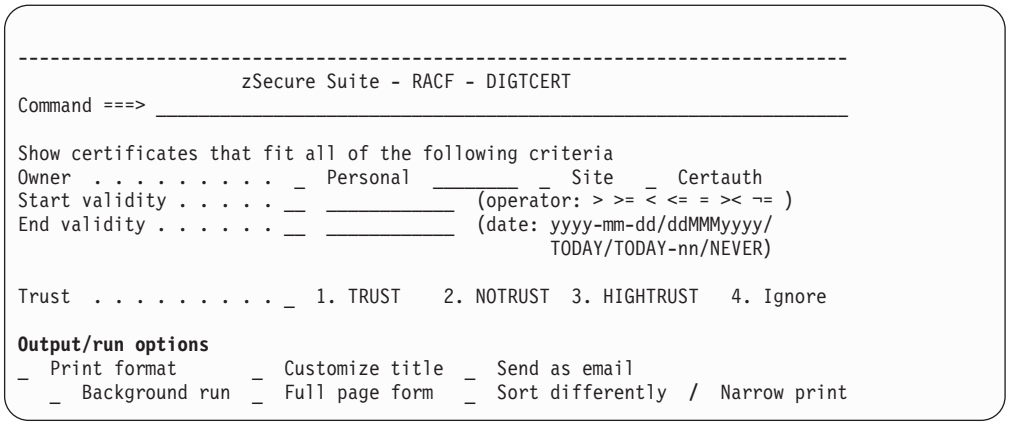

Figure 197. DIGTCERT selection panel

The following selection criteria are available:

Table 151. Digital Certificate reporting- available selection criteria

Selection criteria	Description
Owner	Select certificates for one or more user IDs (PERSONAL), all certificate-authority certificates (CERTAUTH), or all site certificates (SITE). For PERSONAL certificates, you can optionally use filters to select certificates for multiple userids. You can use the percent symbol (%) to select one character and you can use the asterisk symbol (*) to select zero or more characters.
Start validity operator	Use the operator to determine the date for selection. Use < and <= for selection prior to or on the date specified, > or >= for later dates, = for exact dates, ¬= or <> for all but the specified date.
Start validity	The start of the validity of the digital certificates. The date can be specified as: *ddmmmyyyy*, *01jan1998* for example. *yyyy-mm-dd*, *1998-01-01* for example. *TODAY* TODAY-*xx* or TODAY+*xx*where *xx* is a number of days. *NEVER* to indicate that no start validity date has been set.
End validity operator	Use the operator to determine the date for selection. Use < and <= for selection prior to or on the date specified, > or >= for later dates, = for exact dates, ¬= or <> for all but the specified date.
End validity	The end of the validity of the digital certificates. The date can be specified as: *ddmmmyyyy*, *01jan1998* for example. *yyyy-mm-dd*, *1998-01-01* for example. *TODAY* TODAY-*xx* or TODAY+*xx*where *xx* is a number of days. *NEVER* to indicate that no end validity date has been set.
Trust	Selects certificates based on their trusted status.

Table 151. Digital Certificate reporting- available selection criteria (continued)

Selection criteria	Description
CERTAUTH, MULTIID, SITE	Report or suppress CERTAUTH, MULTIID, and SITE certificates. Specify `Y` to only report these certificates, `N` to suppress them, or blank to report all certificates.
Userid	Selects on the user ID associated with a certificate. You can use the following filters to select more than one user ID: `%` for one character and `*` for one or more characters.

You can select the following output and run options by entering / or *S* in the input field for the option.

Table 152. Digital Certificate reporting - output and run options

Option	Description
Print format	If this field is selected, the output data is formatted for printing rather than for ISPF display. When you select this option, other print-related options become active for further customization of the printed report. This flag setting is saved in your ISPF profile and is shared between all RA options showing it. The print format is either tabular or form-oriented. You can select the **Full page form** option if you want the results printed in a form. The tabular format sacrifices some detail in favor of a readable printout. The print format can either use a print file width of at least 132, or forced into 79 columns by selecting the **Narrow print** option. The prints can be sorted differently than by key through the Sort differently checkbox.
Customize title	If this field is selected together with **Print format**, you can change the subtitle for the selection and add an extra title that is saved in your ISPF profile, your company name, department, and phone number for example. This flag setting is saved in your ISPF profile and is shared by all RA options showing it.
Send as email	If this field is selected along with **Print format**, then a panel opens for specifying the email address destination for the report. The email function does not work until you have configured the SMTP options with `SETUP OUTPUT`. This flag setting is saved in your ISPF profile and is shared between all RA options showing it.
Background run	If this field is selected together with **Print format**, then a batch job is submitted to perform the query. This flag setting is saved in your ISPF profile and is shared by all `RA` options showing it.
Full page form	If this field is selected (with a /) as well as **Print format**, then at least a full page per Digital Certificate is printed for including all certificate details. This selection is only effective when selected together with the **Print format** option. This flag setting is saved in your ISPF profile.

Table 152. Digital Certificate reporting - output and run options (continued)

Option	Description
Sort differently	If this field is selected together with **Print format**, then an alternate sort order can be selected. You can change the sort order in an ISPF display panel by issuing the SORT primary command in the ISPF panel. display. This flag setting is saved in your ISPF profile.
Narrow print	If this field is selected together with **Print format**, then the page width is limited to 79 characters, independent of the actual print file record length. If the field is not selected, then the page layout you specify must support a width of 132. However, the length can extend beyond that if the print file has a larger record length. This flag setting is saved in your ISPF profile and shared between all panels that support this option.

Digital certificates tabular display

A sample digital certificates display is shown in the following figure.

```
zSecure Suite  DIGTCERT CERTDATA segments          Line 1 of 5

Figure 198. Digital certificates tabular display panel

The following fields of interest are shown.

Table 153. Digital certificates tabular display fields

Field	Description
Digital certificate labels	The certificate label of the certificate
User	The user ID associated with the certificate
Tru	Indicates whether the certificate is marked as trusted
Cert. sta	The date signifying the start of the validity of this digital certificate
Cert. end	The date signifying the end of the validity of this digital certificate
Complex	The security complex that contains the system. This can come from the ALLOC COMPLEX parameter or default to a system name.

By scrolling to the right, additional fields are displayed:

Field	Description
Issuer's distinguished name	The distinguished name of the issuer of the certificate.
Serial number	The serial number of the certificate.
Key Type	The type of the private key, stored in this digital certificate.

Field	Description
Subject's distinguished name	The distinguished name of the subject of the certificate, for example, the user for whom the certificate was issued.

Digital certificates detail display

Select any row on the digital certificate table display to see the detail view. Selection can be done by putting the cursor on the first character of row selection field and pressing ENTER, or by explicitly typing **S** there and pressing **Enter**.

Figure 199. Digital certificates detail display panel

The following fields of interest can be shown:

Table 154. Digital certificates detail display fields

Field	Description
Digital certificate labels	The certificate label of the certificate
User	The user ID associated with the certificate
Tru	Indicates whether the certificate is marked as trusted
Certificate startdate	The date signifying the start of the validity of this digital certificate
Certificate enddate	The date signifying the end of the validity of this digital certificate
Subject's distinguished name	The distinguished name of the subject of the certificate, which represents the user for whom the certificate was issued.

Table 154. Digital certificates detail display fields (continued)

Field	Description
Issuer's distinguished name	The distinguished name of the issuer of the certificate.
Serial number	The serial number of the certificate.
Private Key Type	The type of the private key, stored in this digital certificate.
Private Key Size	The size, in bits, of the private key, stored in this digital certificate.
Certificate lser	It contains the last eight bytes of the last certificate that was signed with this key.
Certificate AltName email	The email addresses of the subject as found in the `subjectAltName` extension of the certificate.
Certificate AltName domain	The domain names of the subject as found in the `subjectAltName` extension of the certificate.
Certificate AltName IP addr	The IP addresses of the subject as found in the `subjectAltName` extension of the certificate.
Certificate AltName URI	The universal resource identifiers of the subject as found in the `subjectAltName` extension of the certificate.
RACF format	The `keyUsage` extension of the certificate as RACF would show it.
X509 format	The `keyUsage` extension of the certificate as defined by the X.509 standard.
Ring name	A list of full names (`userid` and `keyringname`) of the key rings to which this digital certificate is connected.

RA.C CUSTOM - User Defined Display (Custom Display)

In some situations, the standard display panels might not include fields you are interested in or the display might have the wrong selection or sort criteria. To resolve this problem, Security zSecure provides a method for testing `SELECT` and `DISPLAY` commands.

You can enter up to three `SELECT` commands. Any profile that matches the selection criteria is shown. The selections are combined with `OR` logic. Additionally, you can enter up to three `EXCLUDE` commands. A profile is shown as long as it does not match any of the exclusion criteria. The exclusion criteria are combined with `AND` logic. You can specify the `DISPLAY` command with any field name defined in the templates to select and show those records. Use the `TEMPLATE` primary command to look at the templates. For more information see “TEMPLATE - Template field properties” on page 284. You can also use the variables defined in the C2RXDEF1 member of the `SCKRCARL` library. The fields and variables are also documented in “RACF: RACF profiles” on page 1124.

For ease of use, the User Defined Display panel offers a suggested list of field names for each of the common profile classes. This list is added to the `DISPLAY` field when you type an *S* or `/` before the specific class name. Selecting a different common profile class does not overwrite what you typed in the `SELECT` or `EXCLUDE` fields.

Figure 200 on page 250 shows how some relevant fields are supplied for General Resource profiles.

```
  Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - User defined display
Command ===> ____________________________________________________________

Enter up to 3 SELECT condition sets:
Select  ____________________________________________________________________
Select  ____________________________________________________________________
Select  ____________________________________________________________________
Enter up to 3 EXCLUDE condition sets:
Exclude ____________________________________________________________________
Exclude ____________________________________________________________________
Exclude ____________________________________________________________________
Enter output variables:
Display class(key)_key(44,key)_proftype(1)_uacc_owner_auditlvl_warning(1)_____
        complex_notify_seclabel_creadate_instdata_acl_acl:pgmrname_____________
        acl:instdata_/_appldata(header,"Application Data",20,detail)___________
        ____________________________________________________________________
        ____________________________________________________________________

Select a set of standard report variables for one of these profile classes:
 _  User    _  Dataset  _  Connect  s  General resource with cond.acc.list
 _  Group   _  Tape                _  General resource with member list
```

Figure 200. User-defined display panel

You can put together conditions and fields to fit your requirements of the day. For example, you might want to list all users who have requested a user ID but never used it.

```
  Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - User Defined Display

Figure 202. Custom query output display

The fields you can use in a query are documented in "RACF: RACF profiles" on page 1124.

Predefined CARLa scripts

zSecure provides predefined CARLa (CARLa Auditing and Reporting Language) scripts for creating the sample reports available in the SCKRCARL library. These scripts create reports for product panels and for printing. For information about the naming conventions for CARLa scripts, see "Naming convention" on page 706.

For more information, see the following topics:

- "Interactive reports"
- "CARLa scripts for RECREATE and COPY functions" on page 252
- "Report layouts" on page 252
- "Batch CARLa scripts" on page 253

Interactive reports

Table 155 describes the CARLa scripts for creating reports that display in the zSecure product panels.

Table 155. CARLa scripts to create Interactive reports

Report	Meaning
CKRDNONR	Creates the REPORT NONREDUNDANT sample display. The **RA.3.3** option in zSecure does not use this script.

Table 155. CARLa scripts to create Interactive reports (continued)

Report	Meaning
CKRDPROF	Creates the REPORT PROFILES sample display. The **RA.3.1** option in zSecure does not use this script.
C2RDRAS	Creates the CDT and SETROPTS class info. The **RA.S** in zSecure uses this script.
C2RDRASD	Creates the CDT and SETROPTS class info from database. The **RA.S** in zSecure uses this script.

CARLa scripts for RECREATE and COPY functions

The zSecure interactive component uses these CARLa scripts for COPY and RECREATE functions. The CKRX* CARLa scripts use LIKELIST clauses to refer to preselection NEWLIST statements with NAME=RACFSEL. To run these scripts with your own selections, define a preselection NEWLIST with that name. See "Selecting based on previously specified criteria (LIKELIST)" on page 887.

The CKGX* CARLa scripts can be concatenated with the corresponding CKRX* scripts. CKGX* can refer to RACFSEL either directly or through a specific preselection NEWLIST statement in the CKRX* CARLa script, GROUPS for example. These scripts issue CKGRACF commands in addition to the RACF commands generated in the CKRX* members to complete profile recreation.

Table 156 describes the CKGX* and CKRX* CARLa scripts in the product.

Table 156. CARLa scripts to recreate and copy data and profiles

CARLa script	Function
CKGXRDS	Recreate CKGRACF and user data for DATASET profiles.
CKGXRGR	Recreates CKGRACF and user data for group profiles.
CKGXRRES	Recreates CKGRACF and user data for resource profiles.
CKGXRUS	Recreate CKGRACF data, user data, and TSO data for User profiles.
CKRXCDS	Copy DATASET profile.
CKRXCRE	Copy general resource profile.
CKRXRAC	Recreate access list entries.
CKRXRDS	Recreate a DATASET profile.
CKRXRGR	Recreate a group profile.
CKRXRRE	Recreate a general resource profile
CKRXRUS	Recreate user

Report layouts

The following members contain the original layouts for the REPORT command when used with the indicated parameters. They are automatically included if the REPORT command is encountered with that parameter, while no REPORT_*type* NEWLIST precedes it in the query. (For REDUNDANT and NONREDUNDANT *type* equals NONREDUNDANCY; for the other parameters *type* equals the parameter name itself).

Member	Definitions
CKRREDUN	REPORT REDUNDANT default layout

Member	Definitions
CKRRNOND	REPORT NONDEFAULT default layout
CKRRNONR	REPORT NONREDUNDANT default layout
CKRROUTG	REPORT OUTOFGROUP default layout
CKRRPROF	REPORT PROFILES default layout
CKRRSCOP	REPORT SCOPE default layout

Batch CARLa scripts

Table 157 describes the CARLa scripts for creating reports through batch processing.

Table 157. CARLa scripts for creating reports through batch processing

CARLa script	Function
CKGXLIST	List profiles that require a `CKGRACF` refresh.
CKGXREFR	Create `CKGRACF REFRESH` commands for all profiles that require them.
CKGXUSRW	Create `CKGRACF WIPE` commands for `CKGRACF` and user data for all applicable user profiles.
CKRVDSN	Check consistency and completeness of data set resource protection.
CKRVPROG	Check consistency and referential integrity of program protection.
CKRVPWHC	Create `CKGRACF` commands to convert hashed passwords to DES-encrypted passwords
CKRVRACF	Check RACF database consistency.
CKRVUNIX	Create RACF commands to populate the `UNIXMAP` class.
C2RL$UNL	Create RACF and ACF2 unload and report statistics.

Chapter 3. RACF Audit Guide

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•		

General information

The interactive component of Security zSecure is an ISPF application available under MVS/TSO.

For details on how to start this component, see "Starting the interactive component" on page 9. See "Panel structure" on page 10 for an overview of the panels and instructions for using them.

After selecting the **AU Audit** option, the panel should look similar to the one shown in Figure 203.

```
  Menu         Options       Info     Commands     Setup

5655-T02 IBM Security zSecure Audit for RACF 1.13.0
```

Figure 203. IBM Security zSecure Admin main menu

This section of the documentation focuses on Audit functions. For more information on the Audit menu options, refer to the sections indicated in Table 5-1 the following table. For a table of references for the other main menu options such as RA and EV , see Table 2 on page 11. You can also obtain information about the panels and fields by using the context-sensitive help function available on most panels. To access the help, press PF1 or type HELP.

The options in the Audit main menu are described in different manual sections.

Table 158. Documentation reference for zSecure Menu options

Menu Option	Documentation reference
SE Setup	"SE SETUP - Options and input data sets used" on page 1641

Table 158. Documentation reference for zSecure Menu options (continued)

Menu Option	Documentation reference
RA RACF	Chapter 2, "RACF Administration Guide," on page 51
AU.C	"AU.C Change track" on page 521
AU.L	Chapter 6, "Library Audit Guide," on page 529
AU.S	Information about the part of the AU.S menu option that pertains to an MVS system is provided in "STATUS AUDIT - MVS tables" on page 440 and "STATUS AUDIT - MVS extended tables" on page 499.
AU.V	"AU.V VERIFY - Verify Selection List" on page 353

This Audit Guide includes the following sections:

"Migrating from DSMON": Migration from DSMON.

"AU.S STATUS AUDIT - MVS and RACF security options and tables" on page 257: A description of the STATUS AUDIT menu.

"STATUS AUDIT - OVERVIEW" on page 261: Overall audit concern overview ordered by audit priority.

"STATUS AUDIT - RACF control" on page 266: A discussion of the RACF audit reports.

"STATUS AUDIT - RACF user" on page 291: A description of RACF reports on RACF user IDs.

"STATUS AUDIT - RACF resource" on page 316: A description of RACF reports on the protection of resources, resource profile audit concerns, and database resource usage.

"AU.V VERIFY - Verify Selection List" on page 353: Reports on inconsistencies, and how to solve these.

"Common RACF problems" on page 356: Solutions to some of the most common problems.

"Auditing CKGRACF" on page 371: A discussion on auditing the CKGRACF authorized component.

"Predefined CARLa scripts" on page 377: A discussion of the sample reports available, and their use.

Migrating from DSMON

The DSMON (Data Security Monitor) program is part of the RACF security system. Many auditors use this program for audit reporting and analysis. You can use zSecure to create the equivalent DSMON reports. In addition, zSecure provides many additional reports that provide more detailed and extensive audit reporting.

Use the information in this chapter to learn how to create the equivalent DSMON reports using zSecure. For information about the DSMON program, see the *Security Server RACF Auditor's Guide*.

For information about the reports, see the following topics:

- DSMON System Report See "SYSTEM - MVS system settings report" on page 441.
- DSMON Group Tree Report See "RA.3.8 GROUP TREE - Group tree display" on page 217.
- DSMON Program Property Table Report See "PPT - Program Property Table report" on page 467.
- DSMON Authorized Caller Table Report See "AUTAB - RACF Authorized Caller Table ICHAUTAB" on page 273.
- DSMON Class Descriptor Table report See "RACFCLAS - Class Descriptor Table report" on page 277.
- DSMON Exits Report See "EXITS - Exit and table report" on page 501
- DSMON Global Access Checking report See "GLOBAL - Global Profile overview" on page 283.
- DSMON Started Procedure Table Report See "STCTABLE - Started Procedure Table and Started Class" on page 288, "STCPROT - Started Task protection report" on page 344, and the VERIFY STC command.
- DSMON User Attribute Report See "AUTHSYS - System Authorization reports" on page 297 and "AUTHGRP - Group Authorization report" on page 299.
- DSMON Data Set Reports See "SENSITIVE - Sensitive Data Set report" on page 518, "SENSPROF - Sensitive Data by Profile report" on page 321, "SENSTRUS - Sensitive Data Trustees report" on page 317, and the VERIFY SENSITIVE command.

AU.S STATUS AUDIT - MVS and RACF security options and tables

The AU.S Audit Status option shows the contents of MVS and RACF security tables and settings. The first menu is displayed in Figure 204.

```
 Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Audit - Audit - Status
Command ===> ____________________________________________________________

Enter / to select report categories
_ MVS tables      MVS oriented tables (reads first part of CKFREEZE)
_ MVS extended    MVS oriented tables (reads whole CKFREEZE)
_ RACF control    RACF oriented tables
_ RACF user       User oriented RACF tables and reports
_ RACF resource   Resource oriented RACF tables and reports

 Select options for reports:                                  Audit policy
 _   Select specific reports from selected categories         /  zSecure
 /   Include audit concern overview in overall prio order     _  C1
 _   Only show reports that may contain audit concerns        _  C2
 __   Minimum audit priority for audit concerns (1-99)       _  B1
 _   Print format             _  Concise (short) report
```

Figure 204. STATUS AUDIT menu

The available reports are divided into a number of categories.

- **MVS TABLES** and **MVS EXTENDED** provide audit reports for MVS security tables and settings. For information, see "STATUS AUDIT - MVS tables" on page 440. You can create these reports using zSecure Audit for RACF.
- **RACF CONTROL** provides reports on the global system protection, classes, and database template. These reports do not require a full CKFREEZE read.
- **RACF USER** provides general and detail reports on the RACF users. Typically, these reports generate a **lot** of output. The `TRUSTED` report requires a full `CKFREEZE` read.
- **RACF RESOURCE** provide reports on resource protection for resources like data sets and UNIX files, resource profile audit concerns, and database resource use.

Type a / in the selection field for a report category to open the report selection panels to set up and create the reports.

You can specify the following processing parameters on the report selection panel:

Select specific reports from selected categories
If you select this option, a follow-up report selection panel opens for each selected category. If you do not select this option, all reports in the selected categories are generated.

Include audit concern overview in overall prio order.
This option determines whether an audit concern overview is generated. This overview shows up as the first item in the output. It is sorted by audit priority, and contains a single line for each item for which audit concerns were identified, including an indication of which report the item occurs in. Note that not all reports explicitly identify audit concerns; they are not represented here. The overview spans the categories selected (not just the selected reports). If you select this option without selecting any categories, an overview for all categories is generated. If you only want an overview across a specific category, you can select that category along with the *Select specific reports from selected categories* option, but not select any of the reports.

Only show reports that may contain audit concerns
If you select this option, only the reports that can contain audit concerns are displayed. If *Select specific reports from selected categories* is also requested, only the reports that can contain audit concerns are selectable.

Minimum audit priority for audit concerns (1-99)
Specify the minimum audit priority for audit concerns or leave blank for all records.

Print format
For a foreground run, selecting this option requests to present the output in a printable report format instead of as interactive displays. This is preferable if memory is tight or the output is to be printed. For a detail study of a small amount of data, the interactive display format is generally better suited. For a background run, this option has no effect.

Concise (short) report
If you select this option, some details are omitted from the generated reports. If you are looking for changes or if you are exploring the system, we advise you to select this option; if you want to audit a particular item in depth, you should not use it.

Background run
If you select this option, a background (batch) job is submitted for the

requested reports,which implies output in print format. If you do not select this option, processing proceeds in the foreground.

Audit policy
Use this option to select the audit policy for etermining the audit concerns and priorities. The default audit policy raises the priority value of an audit concern to 40 or more if the system can almost certainly be compromised as a result of the concern. The *C1*, *C2*, and *B1* selections refer to the DoD orange book standards. These values also raise the priority value to 40 or more when a violation of the selected policy is discovered. Specifying these selections does not imply that all violations are noted. In addition, *B1* generates more audit concerns.

If foreground processing is selected, Security zSecure displays the number of `CKFREEZE` records read during processing. After processing, the resulting output is displayed. You can stop report processing by pressing the **ATTN** key.

If background processing is selected, a submit panel is displayed for browsing or editing the generated JCL, and then submit a batch job.

Some reports have additional selection options available to customize the reports. When you select these reports, the panels for these customization options open in sequence so you can specify the settings. You can learn more about the report options available in the report descriptions provided in this manual. When you first use the product, you can leave the selection options blank to use the default values for creating the report. Then, you can study the basic report to determine whether you need to customize the report.

If you select a set of system reports without specifying the disposition options, Security zSecure creates a report selection list with the report types selected as shown in Figure 205 on page 260. The report type list varies depending on what report types you selected from the STATUS - Audit panel (Figure 204 on page 257).

```
zSecure Audit Display Selection                    Line 1 of 84

Figure 205. RACF Security report selection display

The reports in Figure 205 on page 260 provide information about RACF security tables and settings. For more information, see “STATUS AUDIT - MVS tables” on page 440.

For information about MVS security tables and settings, see “STATUS AUDIT - MVS extended tables” on page 499.

zSecure assigns a numerical *audit priority* to each system report entry, indicating the need to review the entry.

- Higher numbers indicate greater concern.
- Numbers 20 and up require review.
- Numbers 40 and up require immediate attention.

Each report entry with a high audit priority also has an associated *audit concern* in text-format. The audit concern summarizes the problem that requires review.

The RACF report types generally have the following structure:

- Summary information sorted by system
- An overview panel,
- A detail panel

Typically, the overview panels are sorted by descending audit priority. That is, the most important entries are listed first. In an overview display, you can view the most important audit concerns by scrolling to the right. In a detail display, you can view all audit concerns by scrolling max down.

STATUS AUDIT - OVERVIEW

The OVERVIEW report at the top of the selection list is a good point to start a system audit. The report summarizes the most important audit concerns across all report types and all systems audited, sorted by numerical audit priority. A pointer to the relevant report type is included. We suggest you view this report first, and then explore the other reports, starting with the reports having the highest audit priority. Figure 206 shows an audit overview display.

Figure 206. RACF Security audit overview display

The overview report contains the following fields of interest:

Field	Explanation
Pri	Numerical audit priority, identifying the severity of the problem. Priorities of 40 and up indicate a very serious concern, requiring immediate attention. Priorities in the range 20 to 39 require review because serious security threats might exist.
Complex	The name of the complex including the system on which the audit concern was identified.
Syst	The name of the system on which the audit concern was identified.
Area	The report type in which the audit concern was identified.
Key	The report key identifying the entry within the relevant report. The value and meaning of the key is report dependent.
Audit concern	The audit concern identified. Background information and audit considerations are explained with each report type.

The following table lists the abbreviations and the NEWLIST types for the various report types. The page numbers refer to the audit concern sections.

Table 159. NEWLIST types - associated report abbreviations and types

Abbreviation	Report type	NEWLIST type
CLAS	Class Descriptor Table	CLASS (page 990)
CONS	Console	CONSOLE (page 1004)
DASD	DASD volume	DASDVOL (page 1013)
DMS	SAMS:Disk parameters	AUDIT (page 961)
EXIT	Exit	EXIT (page 1029)
FILE	UNIX files	UNIX (page 1481)
HSM	Hierarchical Storage Manager	AUDIT (page 961)
IOAP	I/O appendage	IOAPP (page 1052)
JCL	JES2 job class	JOBCLASS (page 1090)
MOUN	Unix Mount Points	MOUNT (page 1104)
MSG	Message Processing Facility	MSG (page 1107)
MVS	MVS Properties	AUDIT (page 961)
PPT	Program Property Table	PPT (page 1122)
RACF	RACF profiles	RACF (page 1131)
SENP	Sensitive profiles	REPORT_SENSITIVE (page 1242)
SENS	Sensitive data sets	SENSDSN (page 1256)
SETR	SETROPTS settings	AUDIT (page 961)
SMF	SMF system settings	AUDIT (page 961)
SMFO	SMF subsystem	SMFOPT (page 1403)
SSCT	Subsystem	SUBSYS (page 1407)
STOR	Writable common storage	CSM (page 1009)
SVC	SuperVisor Call	SVC (page 1417)
SYSL	Syslog settings	AUDIT (page 961)
TRUS	Trusted users and sensitive resources	TRUSTED (page 1476)

Table 159. NEWLIST types - associated report abbreviations and types (continued)

Abbreviation	Report type	NEWLIST type
TSO	TSO settings	AUDIT (page 961)
VSM	Virtual Storage Map	VSM (page 1493)

If you select one of the audit concerns listed with the **S** action character, a detail display is shown.

```

******************************** BOTTOM OF DATA ********************************
```

The detail display layout depends on the report type in which the audit concern was identified; the preceding example shows the layout for a FILE concern. For FILE you usually need to look at the detail display to see what UNIX file it really applies to, since the 11 positions for **Key** on the overview tend to show '...' (meaning that the relative path name really did not fit at all) or '*.../lastqual*'. This example shows that all have write access to file /u/c##qa100/.profile (a=w), while this is a .profile file in some user's home directory, which means it can be executed when that user logs on.

The detail display repeats the following report-independent fields of interest (in full):

Field	Explanation
Complex name	The complex name
System name	The system name
Relative audit priority	The severity of the concern
Audit concern	The audit concern identified

Note: The SENP details omit the system information, as it is not applicable. The TRUS details do not report Complex and System as identification at the top (as multiple systems can be involved).

The detail display also contains a report-dependent section, containing the fields mentioned in the following tables. See “STATUS AUDIT - MVS tables” on page 440 and “STATUS AUDIT - MVS extended tables” on page 499 for information about the following types of data: `CONS`, `DASD`, `DMS`, `EXIT`, `HSM`, `IOAP`, `JCL`, `MOUN`, `MSG`, `MVS`, `PC`, `PPT`, `SENS`, `SMF`, `SMFO`, `SSCT`, `STOR`, `SVC`, `SYSL`, `TSO`, and `VSM` details.

Table 160. CLAS - RACF Class

Field	Explanation
Class name	The class name
Protection active	Whether the class is used for protection
Class description	An explanation of the purpose of the class

Table 161. FILE - UNIX files

Field	Explanation
Absolute pathname	The full pathname of the file.
FS mounted with SECURITY	Whether the file system is mounted with the SECURITY attribute. If not, any user can access and change any file in it.
FS mounted with SETUID	Whether the file system is mounted with the SETUID attribute. Setuid, setgid, APF, and program control attributes are only honored if so.
FS mounted READ/WRITE	Whether the FS is mounted read/write (Yes) or read-only (No).
File type	The type of file: regular file (-), block special file (b), character special file (c), directory (d), external symlink (e), symlink (l), pipe or FIFO (p), socket (s).
File access attributes	The effective file mode, shown as lists of permissions for specific groups. The groups are owner (u), group (g), and other (o). When the permissions of all groups are equal, an (a) is used. The permissions can be read (r), write (w), execute (x), setuid/setgid (s), and sticky bit (t). The setuid/setgid and sticky bits indicators are shown in uppercase (S/T) when execute permission is off. Note that this format is the same as used by the chmod command. These are effective permissions meaning that the mount attributes NOSECURITY and NOSUID as well as the mount MODE (read/write or read-only), and the directories in the file's path have been taken into account.
Extended file attributes	The effective extended attributes, shown as a list of attributes that are on (+) and a list of attributes that are off (-). Possible attributes are APF authorization (a), program controlled (p), address space sharing (s), and library sharing (l).
User id	The `uid` for the file owner.
Owner name	The RACF `userids` mapped to this uid.
Group id	The `gid` for the file.
Group name	The RACF group(s) mapped to this gid.

Table 162. RACF - RACF profiles

Field	Explanation
Class	The profile class.
Profile key	The profile key.

Table 162. RACF - RACF profiles (continued)

Field	Explanation
Universal access authority	The universal access level.

Table 163. SENP - Sensitive profiles

Field	Explanation
Profile type	The profile type.
Profile key	The profile key.
Universal access authority	The universal access level.
Audit access success/failures	The minimum access level for success auditing (if it occurs) and for failure auditing (if it occurs).
Erase-on-scratch	The erase-on-scratch setting for the profile (the SETROPTS setting and HSM settings must also be on for actual erasure on deletion).

Table 164. SETR - SETROPTS settings

Field	Explanation
Parameter name	The RACF parameter.
Parameter value	The value the parameter is set to.

Table 165. TRUS - Sensitive data trustees

Field	Explanation
Complex that may be attacked	The complex for the security database at risk.
System that may be attacked	The system at risk.
Type of sensitive resource	The type of sensitive resource: • *APF library* • *Resource*–a FACILITY profile granting a privilege for example • *Surrogate* – permitting work to be performed under another identity. • *TrustedHome*. The UNIX home directory of a trusted user. • *Privilege*. A privilege affecting the entire system.
Resource class	The resource class, which can be *System*for a system-wide privilege like SPECIAL.
Resource name	The resource name. This value can represent the name of a system for a system-wide privilege.
Volume serial for resource	Volume serial for the resource (if applicable).
Access level that is exposure	The minimum access level that is considered sensitive.
Complex used for the attack	The complex name for the security database where the trusted access is granted.
RACF profile class	The class of the profile which grants access, or an identifier which describes the domain of the privilege.
RACF profile	The security rule by which access is granted.

Table 165. TRUS - Sensitive data trustees (continued)

Field	Explanation
Trusted userid	The user granted trusted access.
Privilege on user's complex	The privilege, security attribute, or operating system function that grants the user access.
Id associated with privilege	The group ID that grants the user access (when access is given via a group.)
Access level granted to user	The access granted if applicable to the privilege.

STATUS AUDIT - RACF control

The RACF reports on global system protection, classes, and database templates do not require a full CKFREEZE read.

More RACF reports are available in the CARLa library or from the main menu options **RA** and **AU.V**. You are advised to run the collection batch report CKRL$ALL, which includes other reports, at least once.

The following RACF reports are described in this section:

- SETROPTS - RACF settings report
- SETROPTD - RACF SETROPTS settings in database
- RRSFNODE - RACF Remote Sharing Facility settings
- ROUTER - SAF router table (ICHRFR01)
- AUTAB - RACF Authorized Caller Table ICHAUTAB
- RANGE - RACF Range Table ICHRRNG
- RACFDSN - RACF Data Set Name Table ICHRDSNT
- RACFCLAS - Class Descriptor Table report
- RACFDCLS - RACF class info from database ICB
- GLOBAL - Global Profile overview
- TEMPLATE - Template field properties
- STCTABLE - Started Procedure Table and Started Class

SETROPTS - RACF settings report

STATUS AUDIT option SETROPTS shows the system-wide RACF options as shown by the SETROPTS command, combined with information from the ICHSECOP module and the CDT. A second report SETROPAU shows the associated audit concerns. These reports are only available on z/OS systems and require system information. You must supply an input set that has at least one of the following data sources: a CKFREEZE data set, Live system, or active RACF allocation.

These reports are only available on z/OS systems and require access to system information from one of the following input data sources: the CKFREEZE data set, live system, or active RACF allocation.

The display contains the following fields of interest.

Table 166. SETROPTS settings Audit concerns panel - field descriptions

Field	Explanation
Pri	The highest priority for any audit concern for this system.
Complex	The complex name for the security database.
System	The system name.
Count	The number of audit concerns for this system.
Pri	A measure for the severity of the audit concern.
Parameter	The RACF setting that causes the audit concern
Value	The value the parameter is set to.
Audit concern	The audit concern identified for this setting.

Select an audit concern for a detail display.

Figure 208. RRSF node properties

The display includes the following fields.

Field	Explanation
Complex	The name of the complex examined.
System	The name of the system examined.
Local node	The RRSF local node.
#Node	The number of target nodes.
TargNode	The RRSF node that the local node is connected to.
TargSysn	The MVS (GRS) system name that has the target node as a local node name.
TStat	State of the target RRSF node. For the possible values, see Table 421 on page 1254.
Loc	Flag field (Yes/No) that reflects whether this node is designated as the local node for this system.
Main	Flag field (Yes/No) that reflects whether this node is designated as the main node for this system.
Prot	Protocol for communication. The value can be APPC (Advanced Program-to-Program Communications), or TCPIP (Transmission Control Protocol Internet Protocol).
LUName	Logical unit name for RRSF connection to the target node if using APPC.
ModeName	SNA mode name that designates the network properties to be used when setting the APPC connection to the target node.
TPName	The APPC transaction program profile name (1–64 characters).
Description	Comment describing the target node.
Address	The host name or IP address entered on the TARGET command when defining an RRSF node with TCP protocol.
PortNum	The port number entered on the TARGET command when defining an RRSF node with TCP protocol.

When a node is selected, the detail panel in Figure 209 is displayed. For options not available in your RACF release, no field value is displayed.

Figure 209. RRSF node details display

ROUTER - SAF router table (ICHRFR01)

The information shown in the ROUTER report depends on the level of the operating system that you are reporting about.

On z/OS 1.6 and higher, the report shows the SAF router table (ICHRFR01) as created by the installation. If the installation chose not to create a Router Table for its local resource classes, an empty ROUTER Report can be shown. In that situation, the default action RACF is taken for all RACROUTE requests. This default action is also taken when the installation router table is present, but no matching entry could be located. On z/OS 1.5 and older, this report shows the combination of the IBM router table (ICHRFR0X) and the installation created router table (ICHRFR01).

After selecting or auto-selecting a system on the summary display, the router table for that system is shown. The columns in the report show the priority, class name, requester name, subsystem name, resulting action, and any audit concerns. The action column shows one of the following values:

- *NONE*, if the corresponding RACROUTE requests are not to be passed to RACF.
- *RACF*, if requests are to be passed to RACF.

The audit concern column might show the value `Class not in CDT`. Because the class has not been defined to RACF, ACCESS requests passed to RACF always return the value `not protected`. If the router table indicates that the request should be passed to RACF, the priority is set to 15. If the router table indicates that these requests should not be passed to RACF anyway, the priority is set to 3.

These reports are only available on z/OS systems and require system information. You must supply an input set with one fo the following data sources: `CKFREEZE`

data set, Live system, or active RACF allocation.

Figure 210. SAF router display

The table is used for requests passed to SAF (System Authorization Facility) through the RACROUTE macro. If the class is not present, or if ACTION=NONE is contained in the Router Table, the request is not passed to RACF. When a class is not defined in the CDT, RACF flags any references to profiles in such a class as errors, returning a 'class not defined' code.

AUTAB - RACF Authorized Caller Table ICHAUTAB

STATUS AUDIT option AUTAB displays the authorized caller table ICHAUTAB used by RACF. Each line indicates a program name, and flags indicating special authorizations. The authorizations are only granted by RACF if the specified program is loaded from an APF-authorized library (does not need to have AC=1).

These reports are only available on z/OS systems and require system information. You must supply an input set that includes at least one of the following data sources: a CKFREEZE data set, Live system, or active RACF allocation.

Background

The authorized caller table is used to define programs to RACF that are permitted to issue RACLIST (RACROUTE REQUEST=LIST) or RACINIT (RACROUTE REQUEST=VERIFY) calls if only they are loaded from an APF-authorized library. They do not need to be actually APF-authorized (have AC=1).

Auditing the RACF Authorized Caller Table

The authorization to obtain a list of profiles can enable a program to obtain information that it cannot access in any other way.

```

   AUTAB    1290           1
Program  RACLIST RACINIT Authorization
AUTH     Yes     No      RACLIST
****************************** BOTTOM OF DATA ********************************
```

Figure 211. Authorized Caller Table display

The display contains the following fields of interest.

Field	Explanation
Complex	The name of the complex examined.
System	The name of the system examined.
Entries	The number of entries in the table.
Program	The program name.
RACLIST	Program can issue RACLIST, enabling you to obtain access to profiles that would normally be inaccessible.
RACINIT	Program can issue RACINIT without NEWPASS.
Authorization	A text summary of the program's authorizations.

RANGE - RACF Range Table ICHRRNG

The STATUS AUDIT option RANGE leads to a display of the database range table ICHRRNG currently in use by the system. Use the scroll keys to scroll forward and backward through the table.

These reports are only available on z/OS systems and require system information. You must supply an input set that includes data sources: a CKFREEZE data set, Live system, or active RACF allocation.

```
RACF Range Table                                                Line 1 of 7

****************************** BOTTOM OF DATA *******************************
```

The range table display shows the RACF data set sequence number and the start key of the range that is directed to this data set. The key is shown both in characters and in hexadecimal representation (though truncated on most terminal types).

RACFDSN - RACF Data Set Name Table ICHRDSNT

The STATUS AUDIT option RACFDSN leads to the data set name table ICHRDSNT display.

These reports are only available on z/OS systems and require system information. You must supply an input set that includes data sources: a CKFREEZE data set, Live system, or active RACF allocation.

Background

The data sets and options used as the RACF database by RACF are initialized from the RACF Data Set Name Table (ICHRDSNT), but can be modified by RVARY commands.

The sequence numbers of the data sets within the database form the basis on which the RACF range table (ICHRRNG) determines which profiles reside in which data set.

Auditing the RACF Data Set Name Table

For each data set sequence number, the primary and duplex data set names are displayed on separate lines:

```
RACF Current database data set names and settings                Line 1 of 6

```

The display contains the following fields of interest.

Table 167. RACF Current database data set names and settings panel - field descriptions

Field	Explanation
Complex	The name of the complex examined.
System	The name of the system examined.
Entries	The number of entries in the table.
DB#	Database sequence number.
Dataset	Data set name.
Volume	Data set volume serial.
R/T	The number of records per track.
Buf	The number of in-storage buffers (of 1 KB for the non-RDS and 4 KB for the RDS).

Table 167. RACF Current database data set names and settings panel - field descriptions (continued)

Field	Explanation
Attributes	The RACF data set attributes. These are: **DataShare** Data sharing mode active, all other members in IRRXCF00 in data sharing mode or read-only. **DataShareR/O** Read-only mode active, all other members in IRRXCF00 in data sharing mode or read-only. **DataShareTrn** Transition mode. After the connect service completes, the system is in data sharing or read-only mode. **RDS** The data set is in Restructured Data Set format (not shown in RACF releases that only support RDS - 1.9.2 and higher). **ShrDASD** The master data set is on shared DASD. **Act** Data set is active (RACF directs I/O to the data set). **Prim** Data set is primary (RACF directs statistics to the data set). **Mstr** This is the master data set (options & templates in use). **Stat** Statistics should be backed up. **Databuf** The buffer can contain both data and index blocks. **CMS** The data set is in CMS minidisk format

RACFCLAS - Class Descriptor Table report

STATUS AUDIT option CDT displays the class descriptor table ICHERCDE and ICHERCDX as well as the in-storage class activity settings, and profile summaries.

When more than one complex has been setup, the first panel displayed is a summary panel so select the complex:

Figure 213. RACF CDT, SETROPTS class info sorted by audit priority

The display is designed to show blank columns if the best protection options are used, as much as possible. See the description of CLASS NEWLIST for full documentation on the class options. Table 168 provides a basic description of the columns.

Table 168. RACF CDT, SETROPTS class info and number of profiles report - column descriptions

Pr	Audit priority (filled in only with a zSecure Audit for ACF2 license).
Class	Name of the class in the Class Descriptor Table
Pos	The POSIT number used for determining the options setting for the class. A RACF command which changes class options for any one class also changes these options for all classes with the same POSIT value.
Grouping	This column is filled in for (member) classes that have a related grouping class.
Members	This column is filled in for (grouping) classes that have a related member class.

Table 168. RACF CDT, SETROPTS class info and number of profiles report - column descriptions (continued)

Protect	This column summarizes a number of options. The most 'offensive' option from the security viewpoint is displayed. The priority order for the displayed values is: • Inactive - The class is not active • Noaudit - Profile changes are not audited.

Glbl	This column summarizes the activity of the global access table for the class: ('Global Active') **Glob** Global access checking is active for the class. This does not mean that there are any profiles on the table. **n/a** Global access checking does not apply to this class because the class cannot be combined with SETROPTS RACLIST. This value applies only if you are examining a very old RACF database.

Generic	If generic profiles are not permitted, this column shows the value *Discrete*; Otherwise, this column is blank.
Profiles	Number of profiles in this class.
RC	Default return code. *0* means grant the request as if a profile permittinng access were present. *4* means 'do not know', in which case what happens is application-dependent. *8* means fail the request as if a profile denying access were present.
Oper	This column contains the text `OPER` if the `OPERATIONS` attribute applies to this class. This means that all users with this attribute have access unless specifically denied access.
RFR	Indicates whether the class is present in at least one entry in the SAF router table.
Id	Generic class identifier.
Org	Original sequence number in the Class Descriptor Table.
UACC	Contains the default universal access setting for profiles created in this class. The value can be any of the following: *ALTER*, *CONTROL*, *UPDATE*, *READ*, *NONE*, or *ACEE.* The last value indicates that RACF uses the default `UACC` of the `ACEE` of the user.

Where	Summarizes the options available to regulate profile residency. The following options are available, listed in order of priority: *Nowhere*. The class cannot have any profile which is indicated by `PROFDEF=NO` in the Class Descriptor Table. *RaclReq*. The profiles are resident if the class is active, because RACLIST is required (RACLREQ=YES option in the CDT). *Raclist*. The profiles are resident (by means of the SETROPTS RACLIST option). *Genlist*. The generic profiles are resident (by means of the SETROPTS GENLIST option). *RaclGbo*. The profiles are resident only because they have been RACLISTed by an application via a RACROUTE macro with GLOBAL=YES specified. *NoList*. The profiles cannot be made resident (due to the RACLIST=DISALLOWED and GENLIST=DISALLOWED options in the CDT). This is typically the case for classes meant to be accessed with RACLIST and FRACHECK by applications. *NoRacl*. The profiles are not resident, and only the generic ones can be made resident (by means of SETROPTS GENLIST). Discrete profiles cannot be made resident (due to the RACLIST=DISALLOWED option in the CDT). *NoGenl*. The profiles are not resident, but can be made so (by means of the SETROPTS RACLIST option); however, it is not possible to make only the generic ones resident (due to GENLIST=DISALLOWED in the CDT). (blank) Both generics and discretes or generics only can be made resident by using SETROPTS RACLIST or SETROPTS GENLIST, respectively.

Max	Maximum length of profiles in this class.
MxE	Maximum length for use with the ENTITY keyword of the RACROUTE macro.
Sta	Statistics are collected for this class.
Scl	Security label is required for profiles in this class.
Rvm	Reverse mandatory access checking is required.
EqM	Equal mandatory access checking is required.
Aud	Command auditing is active for this class.
Logopt	Auditing options for this class; can be *Always, Failure, Never, Success*, and *Profile* (determined by the logging options of the profile).
Discrete	Number of discrete profiles in this class.
Generics	Number of generic profiles in this class.
Act	RACF protection is active for this class.
Glb	Global Access Checking is active for this class.
Gen	Generic profile checking for this class is active.
Gcm	Generic commands permitted for this class.
NoP	Profiles cannot be defined in this class.

Gna	This flag field indicates whether SETROPTS GENERIC and SETROPTS GENCMD are permitted for the class.
RlR	A RACLIST is required for this class.
Rcl	The class is RACLISTed (via SETROPTS RACLIST).
Dsp	RACLISTed profiles for this class have been stored in a dataspace.
Gnl	The class is GENLISTed.
GbO	The class is RACLISTed due to RACROUTE GLOBAL=YES only.
RlA	A RACLIST is permitted for this class.
GlA	A GENLIST is permitted for this class.
Sig	An ENF signal must be sent when the class is being RACLISTed, NORACLISTed, or RACLIST refreshed.
Usr	The class is user-installed (as opposed to IBM-defined).
Qu	The number of qualifiers at the start of the profile name that cannot be generic.
Lwr	The profile name can contain lowercase characters.
S1A	The first character of the profile name can be alphabetical.
S1N	The first character of the profile name can be a national character.
S1#	The first character of the profile name can be numerical.
S1S	The first character of the profile name can be a special character.
SRA	The characters after the first character of the profile name can be alphabetical.
SRN	The characters after the first character of the profile name can be national.
SR#	The characters after the first character of the profile name can be numerical.
SRS	The characters after the first character of the profile name can be a special character.
Description	A short explanation of the purpose of the class.
Audit concern	Any audit concerns identified for this class. If you do not have zSecure Audit for ACF2, no attempt is made to identify any.

The following action commands are available.

E - Display event logging

Searches for for SMF events concerning the class it is issued for.

This command starts option **EV.R** General resource events from SMF for the class it is issued for. See “Reporting on general resource events (EV.R)” on page 567.

P - Display profiles

Searches for all defined profiles in the class it is issued for.

It invokes option **RA.R** RESOURCE for the class it is issued for. See “RA.R RESOURCE - General Resource profiles” on page 147.

R - Refresh class

Refreshes the class it is issued for. The generated commands depend on the current settings for the class. See “REFRESH - Automatic refreshes for RACLIST, GENERIC checking, GLOBAL access checking, and WHEN(PROGRAM)” on page 86.

S - Show additional information

Shows additional information about the class it is issued for on the Class Option Display panel. The panel lists all class options set by the CDT and SETROPTS command, the number of profiles in the database of the specified class, and indicates whether the class is present in the SAF router table.

When a class is selected, the class option panel is displayed. Depending on your RACF release, some fields might be blank because the options they represent are not supported by the RACF database.

```

The columns are designed in such a way that the better the protection options, the less intensified fields are on the display. See the description of the "SETROPTS_CLASS: RACF Class Settings in database" on page 1272 for full documentation of the class options, or call field help by positioning the cursor on the field and pressing PF1.

When a class is selected, the class option panel is displayed. Depending on your RACF release, not all fields can be filled in: options not present in your RACF release are simply left blank.

TEMPLATE - Template field properties

The STATUS AUDIT option TEMPLATE lists the field names defined in the RACF database templates together with the default properties assigned by Security zSecure. If an UNLOAD file or a RACF database copy has not been allocated, you must have READ permit access to the RACF data sets to use the TEMPLATE command. You can run the TEMPLATE command from the command line on most Security zSecure panels. Figure 215 on page 285 shows the template display panel.

```

Figure 215. RACF template definitions display panel

The Template Display shows one line per template or custom field. The first three columns, Entity, Segment, and Field, uniquely identify a field. Entity and Id also uniquely identify a field. The display shows columns that directly reflect fields in the template in the master database, as well as columns with a Security zSecure interpretation. You can scroll left/right and up/down to see all fields and columns. To view a detail display of any field, use the **S** line command to select it.

Table 169 describes the fields included in the Template display.

Table 169. RACF template definitions display panel - field descriptions

Entity	Name of the entity type . This can be GROUP (1), USER (2), CONNECT (3 - non-RDS only), DATASET (4), or GENERAL (5). Classes for entity type GENERAL are further defined in the Class Descriptor Table. The other entity types are reserved.
Segment	Name of the segment containing the field. The base segment can be displayed as `BASE` as well as `Base`. The latter syntax indicates that the field lies in a different segment as far as the templates are concerned for a non-RDS (see APAR OY41581, for example).
Field	The name of the field. You can use this name as a parameter on the SELECT, EXCLUDE, LIST, SORTLIST, DISPLAY, and (D)SUMMARY commands.

Table 169. RACF template definitions display panel - field descriptions (continued)

Id	Number indicating the field id from an RDS-template. The **Id** field is the key field used in the internal representation of the profile to locate a field in a profile. For non-RDS, this value is generated by Security zSecure.
Alias-of	Identifies the field as an alias name for another field. You can use alias field names anywhere in Security zSecure. (The template also has combination fields that identify a combination of fields, but these are not displayed because they are not used by Security zSecure.) The internal template information columns are not filled in for aliases since the template does not contain them.
Group	Name of the count field of the repeat group that contains the field. This name is used by Security zSecure to identify a repeat group.
Bytes	This column gives the field length as it is contained in the template. For fields of varying length, this column displays the value `Varies`.
Dflt	The default value from the template (RDS-only). It shows the value returned by RACF for a field if it is not physically present in the profile.
Format	The default output format used by Security zSecure to display or print the field. If it is blank, the field is displayed *as is*.
Outlen	Default length of the field on output produced by Security zSecure. If this field contains `the value Varies`, there is no default length and list/display produces a ragged column layout unless you provide an overriding length.
Mask	This column shows whether the field is masked or encrypted by default by RACF.
Stat	This column shows whether the field is a statistic.
Sort	This column shows whether the field is stored in sorted order in the template (RDS only).
Pad	Field should be padded with binary zeros on the left side.
VLF	Field is eligible for caching in VLF.
AIM	This column shows whether the field is an Application Identity Mapping alias name
EBC	This column shows for an AIM alias name field whether it contains EBCDIC values
Cnf	This column shows whether the field is confidential (not unloaded)
Dt3	This column shows whether the field contains a 3-byte date
Tmp	The field name is represented in the templates.
DPI	The field name is present as a keyword name in the RACF Dynamic Parse Table.
Sy1	The character set for the first character of a field value.
Sy0	The character set for characters beyond the first.
Mix	The maximum length that can be input for the field.
Maxlen	The maximum length that can be input for the field.
Minval	The minimum value for a numeric field.
Maxval	The maximum value for a numeric field.
Header default	Default column header for LIST family of commands.
Command parm	The parameter used to set or change the value of the field with RACF commands.

Table 169. RACF template definitions display panel - field descriptions (continued)

Command parm fmt	The format to be used for the value of the field when generating RACF commands.
Description	Default prefix header for LIST family of commands.

This panel supports the same commands as in any display panel, SORT, FIND for example.

When you select any row with an **S**, all available information about the field is displayed in a Template Detail panel.

```

You can obtain a full listing of the RACF database templates for a z/OS system using the primary command **TEMPLATE** or the TEMPLATE option available by selecting the RACF Control option on the Audit Status panel (**AU.S**). See "TEMPLATE - Template field properties" on page 284.

STCTABLE - Started Procedure Table and Started Class

STATUS AUDIT option STCTABLE provides details about the identity and level of trust with which the started tasks in the system run. Two displays are provided: One showing the profiles in the started class (STARTED) and one showing the started procedure table ICHRIN03 currently in use (STCTABLE).

These reports are only available on z/OS systems. Because the reports need system information, you need to select an input an input set with a CKFREEZE data set, live system, or active RACF allocation.

Background

When a START command is issued at the console or through the MGCR SVC (SVC 34), RACF 2.1 and up first look for an applicable profile in the STARTED class. With an earlier RACF release, or when no matching profile is found, the started procedure table is checked.

If a match is found, RACF tries to RACINIT with the specified USER and GROUP (if specified). If the user/group combination is invalid, then the started task runs under the default user and group (user * and group * in the ACEE and ++++++++ [2] in the user token. Note that RACF does not look for another match.

The Started Procedure Table simply contains a list of procedure names. The Started Class provides additional granularity by using profiles with two qualifiers (`procedure.jobname`). Each of these qualifiers can be generic. The Started Procedure Table contains discretes, but can contain the entry *.

To match RACF definitions and tables against the actual procedure libraries, see the RACF RESOURCE category report discussed in “STCPROT - Started Task protection report” on page 344 and “Finding inconsistencies in started task definitions” on page 367.

For more information on started task processing, including the STARTED class, see the REPORT STC command (which reports on started task processing) and the VERIFY STC command (which indicates errors in started task definitions). They are described in “REPORT” on page 875 and “VERIFY” on page 942.

STARTED - Auditing the Started Class

The Started Class profiles are a means to provide a RACF identity (user and group) to a started task, and additionally specify whether the task should run privileged or trusted.

Clearly, each task in the system should have a matching entry, and special care should be taken with respect to generic catchalls. A catchall is wanted to avoid a fallback to the Started Procedure Table.

A *.* entry in the Started Class should preferably have a specification =MEMBER for either user or group (but not both). Such an entry ensures that the SPT is not used unless the Started Class is inactive. For such an eventuality it can be wise to have a few SPT entries to ensure the system can at least IPL reasonably.

---

2. The value '++++++++' is the default for the JES undefined user; the actual value is reported in the SETROPTS report in “SETROPTS - RACF settings report” on page 266 under the heading "Job Entry Subsystem options" as "Default uid local UNDEFINEDU", and is generally available in the UNDEFINEDUSER field of the SYSTEM NEWLIST

The STARTED display shows the profiles in the started class. Each line indicates a profile (consisting of two qualifiers, the first indicating the started task name), and the user and group names that are assigned by RACF.

```

Figure 216. STARTED class by procedure

The following fields of interest are shown.

Field	Description
Profile key	The profile name (two qualifiers, each of which can be *).
Userid	The user a matching task should run under.
Group	The group a matching task should run under.
Pri Tru Tra	Should the task run privileged, run trusted, be traced (see below).

The last three columns display flags. These are important since they alter the way RACF processes requests for these started tasks.

Pri	Privileged, for example, all authorization requests are honored without Audit trail.
Tru	Trusted, for example, all authorization requests are honored but with Audit trail.
Tra	Traced, for example, RACF issues message IRR812I when the profile and started procedure are used.

On the detail display, the following extra information about the user profile is shown.

Field	Description
Name	The name field of the user profile.
InstData	The installation data field of the user profile.

STCTABLE - Auditing the Started Procedure Table

Use the Started Procedure Table to provide a RACF identity (user and group) for a started task and also specify whether to run the task using a privileged or trusted access level. You can also perform these functions using the Started Class.

If you use the Started Procedure Table, each task in the system requires a matching entry. You can use an SPT entry with the contents * = STCGRP. The group name (STCGROUP) is a group reserved for holding started task user IDs for an environment that has *list-of-groups checking* configured. For more information, see the *Security Server RACF System Programmer's Guide*.

To safeguard against the eventuality that the Started Class is inactive, create several SPT entries so that the system can restart with one of the other entries.

The STCTABLE display shows the started procedure table ICHRIN03 currently in use. Each line indicates a procedure name, and the user and group names that are assigned by RACF.

Figure 217. SPT overview display

The entries are initially shown in alphabetical order. If a generic entry is defined, this is displayed as the line with * as procedure name.

The following fields of interest are shown.

Field	Description
Procname	The procedure name (or the generic entry *). The report has been sorted on this column, so the generic entry is up front.
Userid	The user a matching procedure should run under.
Group	The group a matching procedure should run under.
Attr	Whether the procedure should run privileged or trusted.

The last column displays flags. These are important, since they alter the way RACF processes requests for these started tasks.

Privileged	All authorization requests are honored without Audit trail.
Trusted	All authorization requests are honored but with Audit trail.

Any of the entries can be selected to view detail information of the started task `userid`.

Figure 218. SPT detail display

In addition, the detail display provides the following information about the user profile.

Name	The name field of the user profile
InstData	The installation data field of the user profile.

STATUS AUDIT - RACF user

This section describes RACF reports on RACF users, detailing special authorizations, password settings and usage, and logons. They generally generate a lot of output, and the TRUSTUSR report requires a full CKFREEZE read. The TRUSTUSR report shows which users could compromise the system because they have sensitive access to the Trusted Computing Base.

More RACF reports are available in the CARLa library or from the main menu options **RA** and **AU.V**. You are advised to run the collection batch report `CKRL$ALL`, which includes other reports, at least once.

The following RACF reports are described in this section:

- TRUSTUSR - Trusted users report
- AUTHSYS - System Authorization reports
- AUTHGRP - Group Authorization report
- SHRDUIDS - Shared UNIX uids and gids reports

- PWINLONG - Exceptional Password Interval reports
- PWEXPIRE - Expired Password report
- PWNOCHG - Initial Password report
- PWAGE - Password and Password Phrase Age reports
- PWTRIES - Failed Logon Attempts report
- LGNEVER - Never Used Userids reports
- LGREVOKE - Inactive Userids report
- LGAGE - Last Logon Date reports

TRUSTUSR - Trusted users report

This report shows the access of users to sensitive resources, grouped by user. A similar report grouped by sensitive resource is “SENSTRUS - Sensitive Data Trustees report” on page 317.

Background

A common audit function is to review who can compromise sensitive resources. For some data sets, updates must be tightly controlled (like , APF data sets, and page/swap data sets). For other data sets read access to the information must be tightly controlled (like the RACF database and page/swap data sets). In Security zSecure, resources are called 'sensitive' if access to them can be used directly or indirectly to bypass normal system security. Users that have such access are called 'trusted'. If a hacker wants to bypass the normal security controls, it is sufficient for him to guess, sniff, or steal the password of any of the trusted `userids`.

Auditing trusted users

The trusted users report can be customized to consider JES2 proclibs used for batch jobs sensitive by checking the 'JES2 JOB proclibs considered sensitive' option on the customization panel of the STATUS AUDIT menu. In a batch job you can achieve the same effect by including the CARLa command SIMULATE SENSITIVE PROCLIB.

A sample display is shown in the following figure.

```

Field	Description
Pri	The highest audit priority found for the complex
Complex	The complex name for the security database.
Trusted userids	The number of trusted users
Pri	The highest audit priority for this sensitivity type
Reasons	The number of reasons that make the user trusted
Userid	The trusted `userid`
Name	The name of the user
RIP	The flags Revoked, Inactive, and Protected
Dfltgrp	The user's default group
InstData	The user's installation data

Select any `userid` for a list of audit concerns.

```

  Volume serial for resource    SHR000
_ System that may be attacked   DINO
  Complex that may be attacked  TODAY
****************************** BOTTOM OF DATA *******************************
```

The display contains the following fields of interest.

Field	Description
Complex used for the attack	The complex where the trusted userid is defined.
Trusted userid	The trusted `userid` followed by the user name and instdata for that ID.
Revoked (may be by date)	Whether the `userid` is revoked. This is determined by the evaluating the revoke flag and the revoke and resume dates.
Inactive, revoked or pending	Whether the `userid` can be revoked due to the `SETROPTS INACTIVE()` setting if the user logged on now.
Password disabled PROTECTED	Indicates whether the `userid` is protected so that it cannot be used for logging on to the system.
Privilege on user's complex	The privilege, security attribute, or operating system function granting the user access.
Id associated with privilege	The group id that grants the user access (when access is given via a group.)
Access level granted to user	The access granted if applicable to the privilege.
RACF profile class	The class of the profile which grants access, or an identifier which describes the domain of the privilege.
RACF profile	The RACF profile covering the resource.
Relative audit priority	A measure for the risk the privilege poses
Audit concern	Explanation how the privilege can be used to obtain the highest system authorization. It can be further annotated for higher priorities.

Field	Description
Access level that is exposure	The minimum access level making a `userid` trusted.
Type of sensitive resource	The type of sensitivity the resource has.
Resource class	The resource class (if applicable).
Resource name	The resource name (if applicable).
Volume serial for resource	Volume serial if relevant for object identification
System that can be attacked	The target system where the resource resides
Complex that may be attacked	The target complex. This value can differ from the complex with the subject and permissive security rule.

In this particular example, user `STRTASK` has `READ` access because of a `PERMIT` (access list entry) for a group to a `DATASET` profile that protects the (primary) RACF database, which contains encrypted passwords. Therefore, this user could try to break a password by encrypting candidate passwords and comparing the results to the value stored in the database.

AUTHSYS - System Authorization reports

These reports show the users that have system-wide special, operations, auditor, or class authorization, or have uid 0 (UNIX superuser authority).

The AUTHSYS report shows the users with system-wide special, operations, auditor, or class authorization. The AUTHUID0 report shows the users with uid 0 in z/OS UNIX.

A sample display for the AUTHSYS report is shown in the following figure.

The detail display lists for each of the user's authorized connections:

Field	Description
User/grp	The group the user is connected to.
Auth	The authority of the connection.
R	Whether the connection is Revoked.
SOA	The group-special, group-operations, and group-auditor flags
AG	The ADSP and Group access flags.
Uacc	The universal access level.
Revokedt	Revoke date for the connection
Resumedt	Resume date for the connection

SHRDUIDS - Shared UNIX uids and gids reports

These reports show what uids and gids (which should preferably be unique, since they are the level at which UNIX security is regulated) are shared by several users or groups.

The SHRDUIDS reports show the uids shared by multiple users. The OMVSNUID report shows the users that have an OMVS segment but do not have a uid assigned. The SHRDGIDS report shows the gids shared by multiple groups. The OMVSNGID report shows the groups that have an OMVS segment but do not have a gid assigned.

A sample display for the SHRDUIDS report is shown in the following figure.

```

__ C##BVC2        5999 EPRISE VC USER       C##BVC   YY
****************************** BOTTOM OF DATA ********************************
```

Field	Description
Userid	The RACF `userid`
OMVS uid	The z/OS UNIX uid (repeated to permit overtype in zSecure Admin).
Name	The user name
Owner	The owner of the user (profile)
RIP	The flags Revoked, Inactive, Protected (cannot logon).
SOA	The flags Special, Operations, Auditor (system authorities).
LastUseDa	The date of the user's last logon.
LastPwdCh	The date of the user's last password change.
LastPhrCh	The user's last password phrase change date.
InstData	Installation data field of the user profile.

The detail display shows the InstData field wrapped.

The SHRDGIDS and OMVSNGID reports are the equivalents of SHRDUIDS and OMVSNUID for groups and gids instead of users and uids. User-specific fields are, of course, not shown--just the InstData.

PWINLONG - Exceptional Password Interval reports

These reports show the user IDs that do not have to change their passwords often based on one of the following profile settings:

- An exceptionally long password interval.
- No password interval specified.
- Can logon without a password.
- Can logon with an OIDCARD.

You can also generate a report showing protected user IDs that do not have a password and cannot logon to the system.

You can generate the following types of reports:

PROTECT
Shows the protected users who have no password and cannot logon. These users are not listed in the other reports.

PWNONE
Shows users that have no password because they have another means of authentication.

PWOID
Shows the users who must supply an operator identification card when logging onto the system.

PWINNONE
Shows the users who never have to change their password because they have no password interval.

PWINLONG
Shows users that have an 'exceptionally long' interval. You can specify the threshold for this interval by editing the PWINLONG NEWLIST statements in the CARLa scripts `CKRDPWIN` and `CKRLPWIN`.

Also, when you configure these reports, you can exclude started task user IDs. If you follow IBM best practices and have configured your system with `list of groups checking` active, you can easily exclude these IDs using the special purpose group *STCGROUP* that the started task user IDs are connected to. You can do this by specifying *STCGROUP* in the select statements for the PWINLONG and PWINNONE NEWLISTs as shown in the following example for the PWINLONG report.

```
select class=user segment=base passint>60 passint<255,
     congrpnm<>stcgroup    /* exclude started tasks */
```

If you define more than 30 characters as *exceptionally long*, and your started tasks are connected to a special STRTASK group, you can customize this statement to specify these conditions as shown in the following example:

```
select class=user segment=base passint>30 passint<255,
     congrpnm<>strtask    /* exclude started tasks */
```

You can also modify the NEWLIST title.

All five reports have the same layout, containing a second-level summary categorizing the user IDs by revoked and inactive status. Inactive user IDs are those that are pending revoke because of a SETROPTS INACTIVE() setting. These IDs are revoked at the next logon attempt. The most interesting category are users that can logon–their access is not revoked or pending revoke.

Figure 219 shows a sample display for the PWINLONG report.

```
Users with password interval > 60 days                          Line 1 of 2
Command ===> ____________________________________________ Scroll===> CSR

Figure 219. PWINLONG report

The display contains the following fields of interest.

Field	Description
Complex	The complex name for the security database.
Timestamp	The date to which the information pertains.
Users	The number of users in the database.
Revoke	Whether the users in the category are revoked.
Inactive	Whether the users in the category are 'pending revoke', for example, if they tried to log on they would be revoked.
Users	The number of users in the category.
Userid	The userid.
Name	The user name.
Int	The password interval.
Eff	Effective password interval: the lowest of user and global interval.
LastPwdCh	The date of the user's last password change.

Field	Description
LastPhrCh	The user's last password phrase change date.
DfltGrp	The user's default group.
Owner	The owner of the userid.
RIRP	The flags Revoked, Inactive, Restricted, and Protected.
SOA	The flags Special, Operations, and Auditor.
gC	Shows whether the user has any group attributes or Clauth authority.
LCX	Shows whether the user has any RACLINKs, any certificates, or an expired password.
Try	The number of unsuccessful password attempts.

The detail display shows the groups the user is connected to, the user's last use date (which reflects both logons and certain updates), the date the user last logged on with any of the groups the user is currently connected to (this reflects the user's last logon date unless the connection to the group the user last logged on with was removed in the interim) [3] , the date the userid was defined, the last password change date, and the installation data.

```

PWEXPIRE - Expired Password report

This report shows the users that have an expired password.

The report has a second-level summary categorizing the userids according to their being revoked and/or inactive (for example, they are not yet revoked, but would be revoked because of the SETROPTS INACTIVE() setting when they next tried to logon) and/or their being unused. The most interesting categories would consist of those users that are able to logon, for example, those that are neither revoked nor pending revoke. Protected userids are excluded.

A sample display is shown in the following figure.

3. For the non-RDS, the last use date is shown here, too.

```
Users with expired passwords                                    Line 1 of 2
Command ===> _____________________________________________ Scroll===> CSR

```

The display contains the same fields as the Exceptional Password Interval reports. Likewise, the detail display shows the groups the user is connected to, the user's last use date, the date the user last logged on with any of the user's current connect groups, the date the `userid` was defined, the last password change date, and the installation data.

The PHEXPIRE report shows the users that have an expired password phrase. It contains the same fields as the PWEXPIRE report.

PWNOCHG - Initial Password report

This report shows the users that appear to have never changed their password. That is, users that have a blank `last password change date`. Protected `userids` are excluded.

The report has a second-level summary categorizing the `userids` according to four criteria:

Recent
Whether these `userids` were only recently created (within the last two weeks); for these `userids` it is probably justifiable that they have an initial password.

Revoked
Indicates if the user is revoked and unable to logon to change the password.

Inactive
Whether the user (although technically not revoked) would be revoked when he attempted to logon now due to the SETROPTS INACTIVE() setting. This does not happen if the `userid` has never been used–the Last use date is empty.

STCgroup
Whether the `userid` is a started task. In order for this indication to function correctly, you might need to customize the determination criterion in the CKRDPWNU and CKRLPWNU CARLa scripts utilized in this report. For example, fill in the correct connect group name (congrpnm) to recognize started tasks by in the where clause of the DEFINE STCGROUP statement (the default is STCGROUP). Also see the example in “PWINLONG - Exceptional Password Interval reports” on page 302.

A sample display is shown in Figure 220 on page 306.

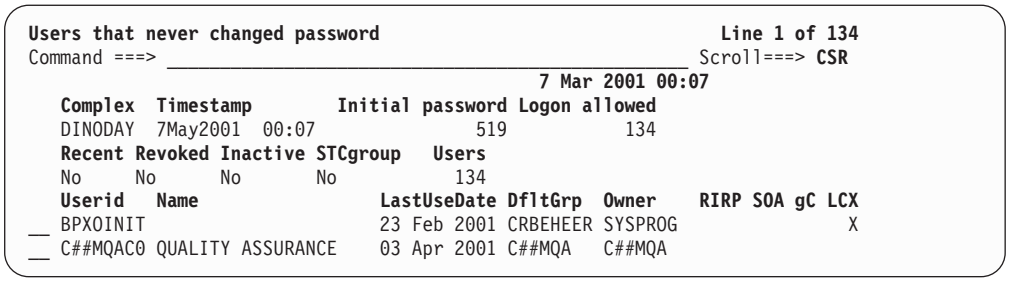

Figure 220. Users that never changed password panel

Table 170 provides the descriptions for the fields of interest on this panel.

Table 170. Users that never changed password - field descriptions

Field	Description
Complex	The complex name for the security database.
Timestamp	The date and time to which the information pertains.
Initial password	The number of users in the database that have an initial password.
Logon allowed	The number of users with an initial password that can successfully logged on. That is, the user ID is neither revoked nor inactive.
Recent	Whether the user IDs in the category were defined within the last two weeks.
Revoked	Whether the user IDs in the category are revoked.
Inactive	Indicates if the user IDs in the category are *pending revoke*. That is, if they tried to log on they would be revoked.
STCgroup	Whether the `userids` in the category are started tasks (if you properly customized the recognition criterion).
Users	The number of `userid` in the category.
Userid	The user ID.
Name	The user name.
LastUseDate	The date of the user's last logon.
DfltGrp	The user's default group.
Owner	The owner of the `userid`.
RIRP	The flags Revoked, Inactive, Restricted, and Protected.
SOA	The flags the Special, Operations, and Auditor attributes.
gC	Shows whether the user has any group attributes or Clauth authority.
LCX	Shows whether the user has any RACLINKs, any certificates, or an expired password.
Try	The number of unsuccessful password attempts

The detail display shows the groups the user is connected to, the user's last use date, the date the user last logged on with any of the user's current connect groups, the date the `userid` was defined, the last password change date, the last password phrase change date, and the installation data.

The PHNOCHG report shows the users that have never changed their password phrase. It contains the same fields as the PWNOCHG report.

PWAGE - Password and Password Phrase Age reports

The Password age overview report summarizes the following password data for all user IDs:

- Security database identification information and a summary of password information that includes the total number of user IDs, user IDs that still use the initial password, and user IDs with an active, non-revoked password.
- User IDs reported by password status: Non-revoked (active and available for log on), pending, or revoked.
- Number of user IDs with a password that has never changed.
- The Passwords listed by password age, which indicates the time elapsed since the last password change.

  The reports lists passwords age by year for passwords older than a year and by month for passwords that have changed within the past year.

Figure 221 shows the Password age overview report.

```

Figure 223. RACF User Password or Phrase Age report

This display contains the following fields of interest.

Field	Description
Complex	The complex name, that is the database).
Timestamp	The date to which the information pertains.
Users	The number of users in the database with a password age in between two and three years.
Revoke	Whether the users in the category are revoked.
Inactive	Whether the users in the category are 'pending revoke', for example, if they tried to log on they would be revoked.
Users	The number of users in the category.
Userid	The user ID.
Name	The user name.
LastPwdCh	Date of the last password change.
LastPhrCh	The date of the last password phrase change.
DfltGrp	The user default group.

Field	Description
Owner	The owner of the user ID.
RI	Flags that indicate if the user ID status is *Revoke* or *Inactive*. or inactive.
SOA	The flags Special, Operations, and Auditor.
Try	The number of unsuccessful password attempts.

The detail display shows the groups the user is connected to, the user's last use date, the date he last logged on with any of his current connect groups, the date the `userid` was defined, the last password change date, the last password phrase change date, and the installation data.

Note: In print format, the equivalents of the `PWAGEALL` and `PWAGE0YR` fields are not supported. They contain information that is available in other entries so it is not necessary to include them in the report.

PWTRIES - Failed Logon Attempts report

This report shows the users that tried to logon with an invalid password and did not successfully complete a logon since. The second summary level shows the different counts of subsequent invalid password attempts, and the number of users for each count. (If you are only interested in this summary level, you can use the concise display).

A sample (detailed) display is shown in the following figure.

```
Users with logon failures                                          Line 1 of 1
Command ===> _____________________________________________ Scroll===> CSR

****************************** BOTTOM OF DATA ********************************
```

This display contains the following fields of interest.

Field	Description
Complex	The complex name (for example which database).
Timestamp	The date and time to which the information pertains.
Users	The number of users with logon failures.
PwTry	The number of failed attempts.
Users	The number of users with this number of failed attempts.
Userid	The `userid`.
Name	The user name.
LastUseDate	The date of the user's last logon.
DfltGrp	The user's default group.
Owner	The owner of the `userid`.
RIRP	The flags Revoked, Inactive, Restricted (user has no access via GAC, UACC, and ID(*)), and Protected (user cannot logon).

Field	Description
SOA	The flags Special, Operations, Auditor (user has system authority).
Try	The number of unsuccessful password attempts.

The detail display shows the groups the user is connected to, the user's last use date, the date he last logged on with any of his current connect groups, the `userid`'s definition date, the last password change date, the last password phrase change date, and the installation data.

LGNEVER - Never Used Userids reports

This report shows the users that appear to have never been used (that is, userids that have an uninitialized last use time). One thing to keep in mind is that `userids` that have never been used are not subject to SETROPTS INACTIVE() processing, when the userids have been created on a system older than z/OS 1.7.

The report has a second-level summary categorizing the user IDs based on the following criteria:

Recent
Whether these user IDs have been created within the last two weeks. For recently created user IDs, it is probably justifiable to not yet have been used.

Revoked
Whether the `userid` is revoked, and therefore cannot be used at present.

Inactive
Whether the user (although technically not revoked) would be revoked when the user attempted to logon now due to the SETROPTS INACTIVE() setting. (=No)

Protected
Whether the user is protected (that is, does not have a password and cannot logon).

STCgroup
Whether the `userid` is a started task. In order for this indication to function correctly, you might need to customize the determination criterion in the CKRDLGNU and CKRLLGNU CARLa scripts utilized in this report. To customize the criterion fill in the correct connect group name (`congrpnm`) to recognize started tasks in the where clause of the DEFINE STCGROUP statement (the default is STCGROUP). See also the example in "PWINLONG - Exceptional Password Interval reports" on page 302.

A sample display is shown in Figure 224 on page 311.

```

Figure 224. User IDs that have never been used report

The display panel contains the following fields of interest.

Field	Description
Complex	The complex name (for example which database).
Timestamp	The date and time to which the information pertains.
Never used	The number of users in the database that have never been used.
Logon allowed	The number of users that have never been used that can successfully logon. That is, the user ID is neither revoked nor inactive.
Recent	Indicates if the user IDs in the category were defined within the last two weeks.
Revoked	Indicates if the user IDs in the category are revoked.
Inactive	Indicates if the user IDs in the category are *pending revoke*. That is, the password for the user ID is revoked at the next logon attempt.
Protected	Indicates if the user IDs in the category are protected.
STCgroup	Indicates if the user IDs in the category are started tasks. This value is reported (if you properly customized the recognition criterion).
Users	The number of user IDs in the category.
Userid	The user IDs.
Name	The user name.
LastPwd	The date of the last password change for the user ID.
LastPhr	The last password phrase change date for the user ID.
DfltGrp	The default group for the user.
Owner	The owner of the user ID.
RIRP	Flag fields that indicate the password status: • **R**evoked • **I**nactive • **R**estricted (user has no access through `GAC`, `UACC`, and `ID(*)`. • **P**rotected (user cannot logon).
SOA	Flag fields indicating the following special authority: • Special • Operations • Auditor (user has system authority)
Try	The number of unsuccessful password attempts.

Select a user ID entry in the report to view the following detailed password and password phrase nformation:

- Groups the user is connected to.
- Last use date.
- Date last logged on with any of the current connect groups.
- User ID definition date.
- Last password change date.
- Last password phrase change date.
- Installation date.

LGREVOKE - Inactive Userids report

These reports show which systems take measures to revoke users that have not logged on for too many days, and for those that do, which users would be revoked due to inactivity if they tried to logon.

LGNOREV - Systems that do not revoke users due to inactivity

The systems listed specify SETROPTS NOINACTIVE and thus take no measurements against `userids` that are no longer used. There are no further details available.

A sample display is shown in the following figure.

```
Systems that do not revoke users due to inactivity              Line 1 of 1

Userid	The `userid`.

Field	Description
Name	The user name.
LastConDate	Estimate of the user's last logon date; for the RDS, the maximum of the RACINIT dates for the user's connect groups; for the non-RDS, the user's last use date.
DfltGrp	The user's default group.
Owner	The owner of the `userid`.
RIRP	The flags Revoked, Inactive, Restricted (user has no access via GAC, UACC, and ID(*)), and Protected (user cannot logon).
SOA	The flags Special, Operations, Auditor (user has system authority).
Try	The number of unsuccessful password attempts

The detail display shows the groups the user is connected to, the user's last use date, the date the user last logged on with any of the user's *current* connect groups, the date the `userid` was defined, the last password change date, the last password phrase change date, and the installation data.

LGAGE - Last Logon Date reports

The Last Logon Summary report summarizes the user population according to the length of time the users have not logged on, and the revoke and pending revoke statuses. The Last Logon Details report shows the user population similarly broken into categories.

For the RDS we use the date of the last logon with any of a user's current connect groups as the best estimate of the last logon date; note that if the connection to the group the user last logged on with is removed in the interim, this cannot be accurate. For the non-RDS use the LJDATE to capture all logon events. The LJDATE is also updated with certain updates. If you want to revert to the prior practice of using the LJDATE for the RDS too, you can edit the following CARLa script members. Change LAST_CONNECT_DATE into LJDATE except where it occurs as `last_connect_date(detail,prefix)` in the detailed display in addition to LJDATE

- CKRDLGAG (summary display)
- CKRLLGAG (summary list)
- CKRDLGAD (detailed display)
- CKRLLGAD (detailed list)
-

Figure 225 on page 314 shows a sample summary.

Figure 225. RACF last logon overview panel

The summary line at the top shows the complex name (which database) with time stamp, the number of users in the database, how many of them have never yet logged on, and how many of those could now successfully logon, for example, they are neither revoked nor inactive.

The section that follows shows the number of userids that are either active or inactive, followed by the total number of userids. The next row shows the number of userids that have never logged in.

The last sections show the number of userids that did log on broken down per year. The last year is broken down further.

The Last Logon Date Details report uses the same dimension, plus the protected attribute. On the first level (which even precedes the database selection level), you select the time interval you are interested in as shown in the following figure.

```

Figure 227. User Display screen

This display contains the following fields of interest.

Field	Description
Complex	The complex name (for example which database).
Timestamp	The date to which the information pertains.
Users	The number of users in the database with a password age in between two and three years.
useridRevoke	Whether the users in the category are revoked.
Inactive	Whether the userids in the category are pending revoke, for example, if they tried to log on they would be revoked.
Protected	Whether the userids in the category are protected.
Users	The number of users in the category.
Userid	The userid.
Name	The user name.
LastConDate	Estimate of the user's last logon date; for the RDS, the maximum of the RACINIT dates for the user's connect groups; for the non-RDS, the user's last use date.
DfltGrp	The user's default group.

Field	Description
Owner	The owner of the `userid`.
RIP	The flags Revoked, Inactive, and Protected (user cannot logon).
SOA	The flags Special, Operations, Auditor (user has system authority).
Try	The number of unsuccessful password attempts.

The detail display shows the groups the user is connected to, the user's last use date, the date the user last logged on with any of the user's current connect groups, the date the `userid` was defined, the last password change date, the last password phrase change date, and the installation data.

Note: In the print format, the equivalents of the LGAGEALL and LGAGE0YR fields are not present in the report because this information is already included in other fields in the report and would be redundant in the printed report.

STATUS AUDIT - RACF resource

This section describes RACF reports on the protection of resources (for example, data sets), resource profile audit concerns, and database resource usage (for example, size). The reports that include data sets require a full CKFREEZE read.

More RACF reports are available in the CARLa library or from the main menu options **RA** and **AU.V**. You are advised to run the collection batch report `CKRL$ALL`, which includes other reports, at least once.

The following RACF reports are described in this section:

- RACPRAUD - RACF Resource Profile Audit Concerns report
- SENSTRUS - Sensitive Data Trustees report
- SENSPROF - Sensitive Data by Profile report
- ENTITY - Entity and segment summaries
- APFPROT - Authorized Programs reports
- PADS - Program Access to Data Sets report
- STCPROT - Started Task protection report
- GLBW - Globally writable data reports
- UIDNOUSR - UNIX ids used in the file system, but not defined to RACF

RACPRAUD - RACF Resource Profile Audit Concerns report

This report shows audit concerns for general resource profiles. A sample display is shown in the following figure.

```

****************************** BOTTOM OF DATA ******************************
```

The audit concerns that can occur are documented in “RACF: RACF profiles” on page 1124.

SENSTRUS - Sensitive Data Trustees report

A common audit function is to review who can compromise sensitive resources. For some data sets like the RACF database, APF data sets, and page/swap data sets, updates must be tightly controlled. For other data sets, , read access to the information must be tightly controlled. In zSecure, sensitive resources are those that can be accessed and used directly or indirectly to bypass normal system

security. Trusted users are those that have access to these sensitive resources. If a hacker wants to bypass the normal security controls, it is sufficient for him or her to guess, sniff, or steal the password of any of the trusted user IDs.

You can use the Sensitive Data Trustees report to audit sensitive resources and review the user access to these resources. The information reports the user access, grouped by sensitive resource type. To see similar information grouped by user, see the "TRUSTUSR - Trusted users report" on page 292.

Auditing sensitive data

You can customize the Sensitive data trustees report to audit JES2 procedure libraries used for batch jobs that are considered sensitive by checking the **JES2 JOB proclibs considered sensitive** option on the customization panel of the STATUS AUDIT menu. You can achieve the same effect in a batch job by including the CARLa command SIMULATE SENSITIVE PROCLIB.

Figure 228 shows a sample of the Sensitive data trustees report.

Pri	The highest audit priority for this user/resource pair.
Userid	A user with sufficient authorization to compromise the resource.
Name	The name of the user.
From	The complex from where the user can compromise the resource.
Audit concern	An explanation of the risk.
Pri	The audit priority for this user/resource/profile triple.
Privilege	The kind of authorization instrumental for the access.
Via	The group id that grants the user access (when access is given via a group.)
Access	The access level granted to the user on the 'From' complex.
Profile	The profile key in the 'From' complex covering the resource.

The detail display panel shown in Figure 231 on page 321 reports the user access information in the following categories: object at risk, the rule that grants the sensitive access, and the subject (user ID) that is trusted.

```
Sensitive data trustees

****************************** BOTTOM OF DATA ********************************
```

Figure 231. Sensitive data trustees report - field descriptions for user access view

This example shows user *C##BERT*, who is trusted because he can update the `.profile` of trusted user *R##SLIN* because he is the file owner. `.profile` is a script executed when a user logs on to the z/OS UNIX system. The full UNIX path name of the `.profile` is shown in Figure 231 and any write access is considered sensitive as indicated by the value *WRIT-NX*.

SENSPROF - Sensitive Data by Profile report

A common audit function is to verify that sensitive data sets are adequately protected. For some data sets (like APF data sets, security databases, and page/swap data sets), updates must be tightly controlled. For other data sets (security database, page/swap data sets), read access to the information must be tightly controlled. zSecure Collect recognizes some sensitive data sets automatically, and Security zSecure verifies RACF protection according to either *confidentiality* or *integrity* demands. The automatically checked sensitive data sets are:

- APF data sets (integrity)
- LPA data sets (integrity)
- Page data sets (confidentiality and integrity)
- Swap data sets (confidentiality and integrity)
- RACF data sets (confidentiality and integrity)
- RRSF data sets (confidentiality and integrity)
- SMF recording data sets (confidentiality and integrity)
- System dump data set (confidentiality and integrity)
- TSO user administration data set UADS (confidentiality and integrity)
- Other system data sets: SYS1.NUCLEUS and SYS1.LPALIB (integrity).
- JES2 and JES3 checkpoint data sets (confidentiality and integrity)

- JES2 and JES3 spool data sets (confidentiality and integrity)
- JES2 and JES3 parameter data set (confidentiality and integrity)
- JES2 and JES3 STC/TSU proclib (integrity)
- MSTR proclib (integrity)
- MSTR parameter library (integrity)
- MSTR VIO administration (integrity)
- DFHSM data set BCDS, MCDS, OCDS (integrity)
- HFS data sets (integrity)
- DMS database DMSFILES (integrity)
- DMS authorized parameter library (integrity)
- DMS default parameter library (integrity)
- CA1 tape management catalog TMC (integrity)
- DFSMS SCDS and ACDS (integrity)
- IODF file, if DSN could be found (integrity)
- Couple data sets (integrity)
- RMM control dataset (integrity)
- TLMS volume master file VMF (integrity)
- ABR archive control file ACF (integrity)

You can audit the sensitive data set protection by generating the Sensitive Data by Profile report which shows the sensitive data sets and their protection, organized by covering profile.

Notes:

1. This report does not treat all systems equally, so be careful not to select multiple input sets on different systems.
2. The intended report to simply look at sensitive data sets in an MVS system without particular regard to their protection is the Sensitive Data Sets report in the MVS EXTENDED category. See “SENSITIVE - Sensitive Data Set report” on page 518.

Background

You can add your own data sets by means of the SIMULATE SENSITIVE command. For more information, see “SIMULATE” on page 911. LINKLIST data sets are automatically reported as APF data sets, unless the IEASYS*xx* member in your system contains LNKAUTH=APFLST. If LINKLIST data sets are not automatically APF authorized, you can use the SIMULATE SENSITIVE LINKLIST command to report LINKLIST anyhow. SIMULATE SENSITIVE PROCLIB can be used to flag integrity problems in the JES2 proclibs used for batch jobs.

Auditing Sensitive Data

When ensuring that all sensitive data sets are adequately protected and audited, a particular audit concern is that the APF list is up to date. If a library contained in the APF list or an authorized library in the LNKLST concatenation does not actually exist on the system, users can create their own data set and then rename it to have the name of the missing APF library, thus creating their own authorized programs. Missing data sets are marked as *notfnd* in the report.

The information included in the sensitive data report can be customized using the following options:

System
Specify a system to be used for primary point of view.

All datasets
Show all data sets that are covered by the profiles that cover any sensitive data sets.

Linklist sensitive
Consider all LNKLST concatenation data sets to be sensitive, for example, even if the LNKLST concatenation is not authorized.

Proclib sensitive
Consider all JES2/JES3 JOB proclibs to be sensitive.

When using the STATUS AUDIT menu, you can simply specify the desired options in the customization panel.

When generating this report with a batch job, you can specify the desired options with CARLa commands included with the standard scripts as listed in the following table.

Table 174. Sensitive data set report - CARLa commands for batch reporting

Information to include in report	CARLa statement
System	DEFAULT SYSTEM= *smf_id*
All data sets	REPORT DATASETS
Linklist sensitive	SIMULATE SENSITIVE LINKLIST
Proclib sensitive	SIMULATE SENSITIVE PROCLIB

In addition, you can also identify additional sensitive data sets to be included with the SIMULATE SENSITIVE command. For details, see "SIMULATE" on page 911. When using the STATUS AUDIT menu, you can put these additional commands in your preamble using the primary command "SETUP 3".

Figure 232 shows the display panel with the Profiles covering sensitive data sets report.

Figure 232. Profiles covering sensitive data sets

The display contains the following fields of interest.

Field	Description
Complex	The complex name of the system used as the primary viewpoint.
Timestamp	The date and time the information pertains to.
Profiles	The number of profiles and High-level qualifiers reported.

Field	Description
Audit concerns	The number of profiles and High-level qualifiers for which audit concerns were found.
Priority	The highest audit priority found for any profile or High-level qualifier.
Pri	The audit priority for the profile or High-level qualifier.
Profile key	The profile key, or the High-level qualifier if no covering profile was found.
UACC	The universal access level.
Era	Whether erase-on-scratch is active for the profile.
S/F	The lowest access level that results in auditing for successes and failures, respectively. The values for the success access level and the failure access level are separated by a blank.
Audit concern	Audit concerns identified.

A detail display is shown in the following table.

The detail display shows the following extra fields.

Table 175. Profiles covering sensitive data sets - detail display field descriptions.

Field	Description
Type	For a data set, either the resource type (see the first table below) or 'notfnd' for a missing APF library; for a profile, the profile type, or (for a High-level qualifier) 'missing' if no profile was found.
Sensitivity	Indication why this data set is considered sensitive.
Volume	The volume serial of the data set
Profile key/ data set name	The profile key (or HLQ) followed by the sensitive data sets covered
Access list	The access list of the profile
Audit concern	Any identified audit concerns (see the second table below)

The resource types that can be shown are listed in the following table.

Table 176. Profiles covering sensitive data sets - resource types

nvsam	Non-VSAM disk data set, migrated if volume is MIGRAT (for HSM or ABR), or archived if the volume is ARCIVE (for DMS). This information is obtained from the VTOC for data sets on disk, the HSM MCDS and the ABR ACF for migrated data sets, and the DMSFILES data set for archived data sets. The information is not derived from the catalog entries.
clustr	VSAM cluster (catalog entry). The volume listed is the volume of the catalog. The source for the cluster names can be a catalog, HSM MCDS, ABR ACF, DMS DMSFILES data set, or VVDS.
bkpclu	Backup of a VSAM cluster. Normally, this is only listed below a backed-up discrete profile such as a discrete profile with a system-generated name. The source for the cluster name is the HSM BCDS or a DMS DMSFILES data set.
index	Index component of a VSAM cluster residing on the indicated DASD volume.
data	Data component of a VSAM cluster residing on the indicated DASD volume.
aixix	Index component of a VSAM alternate index residing on the indicated DASD volume.
aixda	Data component of a VSAM alternate index residing on the indicated DASD volume.
migcl	Migrated or archived VSAM cluster. This is listed below a cluster entry instead of the components. The volume is equal to MIGRAT or ARCIVE.
clust	Backup of VSAM cluster. This is listed below a `bkpclu` entry instead of the components. The volume is equal to MIGRAT or ARCIVE.
gdg	Base name of a GDG (Generation Data Group), obtained from a catalog.
cnntap	Cataloged, unmanaged tape file, on an unmanaged volume.
unntap	Uncataloged, non-managed tape file, on a non-managed volume. The source for such an entry is probably the TVTOC of a TAPEVOL profile.
cmmtap	Cataloged, managed tape file on a managed, non-scratch tape volume.
ummtap	Uncataloged, managed tape file on a managed, non-scratch tape volume.

Table 176. Profiles covering sensitive data sets - resource types (continued)

cnmtap	Cataloged, unmanaged file on a managed, non-scratch volume. This means that the catalog entry conflicts with the tape management information.
unmtap	Uncataloged, non-managed file on a managed, non-scratch volume. The source for such an entry is probably the TVTOC of a TAPEVOL profile.
cnstap	Cataloged, non-managed file, on a managed volume in scratch status.
unstap	Uncataloged, non-managed file, on a managed volume in scratch status. The source for such an entry is probably the TVTOC of a TAPEVOL profile.
secvol	Secondary volume of a multi-volume data set.

The audit concerns that can be identified are shown in the following table.

No erase	Erase on scratch required for confidentiality
No read audit	Read audit required for confidentiality
No update audit	Update audit required for integrity
No alter audit	Alter audit required for integrity
Read fail audit	Read failure audit required for confidentiality
Update fail audit	Update failure audit required for integrity
Alter fail audit	Alter failure audit required for integrity
UACC too high	Universal access should be NONE or READ
Warning mode access	Warning mode on profile resulted in ALTER access
Global access	The access given through the Global Access Table is too high
Unprotected	There is no profile protecting the data set, and PROTECTALL(FAILURES) is not set
ID(*) too high	ID(*) on the access list has too high access

ENTITY - Entity and segment summaries

STATUS AUDIT option ENTITY displays reports that show the number of segments defined and the amount of space used, summarized by entity type and segment.

The ENTITY#S report summarizes by entity type, which means that all GENERAL classes are grouped together. Figure 233 provides an example of the overview display panel.

Figure 236. Entity segment type profile classes report - display panel

APFPROT - Authorized Programs reports

The authorized program reports show the protection of load modules that have the potential to circumvent RACF. This report includes the following information:

- AC(1) members of all APF libraries with all their entry points.
- Modules in APF libraries that are present in the Program Property Table (PPT) with the BYPASS option or a system key (0-7).
- Modules in APF libraries that are present in the RACF authorized caller table with RACINIT or RACLIST authorization.

For z/OS UNIX, the files that run with APF authorization are shown, as well as program-controlled files, and files that run under the file owner identity rather than the identity of the user running them (SETUID/SETGID).

Background

The TSOAUTH, LPAPROT, and APFPROT reports include the highest access to arbitrary users as given by the combined action of the PROGRAM profile UACC, the DATASET profile UACC, the LNKLST concatenation residency, the LPA residency, the global access table, and the profile warning mode. In addition, the report shows all module occurrences with LNKLST concatenation and LPA list concatenation numbers, the MLPA residency in-storage, the base member names for alias entries, the authorizing attributes, the attributes extending the authorization to the TSO environment (AuthCMD AuthPGM AuthTSF), and the RACF profile member names.

Note: These reports do not treat all systems equally, so be careful about multiple input sets.

You can specify a minimum universal access level of interest for entries to be included in these reports, as well as the system to be used as the primary viewpoint for these reports. If you use the STATUS AUDIT menu, you are automatically prompted with a customization panel to select reporting options for the access level and the SMF id for the primary system. In a batch run, these options are set with the CARLa commands REPORT ACCESS= level or DEFAULT SYSTEM=*smf_id*, respectively.

The meaningful access levels that can be specified are shown in the following table.

Table 177. APFPROT - UACC levels and descriptions

Level	Meaning
ALTER	ALTER access.
CONTROL	CONTROL access.
UPDATE	UPDATE access.
READ	READ access.
READLPA	The UACC does not grant READ access, but the module can be read in the LPA.
LOADEXE	The UACC does not grant READ access, but the module can be executed and read using LOAD.
EXECUTE	Execute access.
COPY	A module can be read, but not executed. If the operation does not depend on APF or library residence, then anyone can access its functionality by copying it to his or her own load library.
HIDDEN	A PDS member or load module hidden by a similarly named member in a library in front of this library.

The UNIXAPF, UNIXCTL, UNIXSUID, and UNIXSGID reports show the z/OS UNIX files that run with the following attributes: APF authorized, program-controlled, SETUID and SETGID, respectively.

APF authorization attribute
Files with the extended attribute *a* run APF authorized. The FACILITY resource BPX.FILEATTR.APF setting determines who can enable the APF authorization.

Program-controlled attribute
Files with the BPX.FILEATTR.PROGCTL protects the *p* extended attribute (program control). Together with UPDATE access to one of the FACILTY profiles BPX.DAEMON or BPX.SERVER, a controlled environment permits process or thread identity switches.

If BPX.DAEMON has `READ` access and `UID=0`, identity switches with the `spawn` and `SETUID` attributes are permitted.

`SETUID` and `SETGID` attribute
The `SETUID` and `SETGID` attributes basically mean that a program runs under the identity of the file owner (`UID` or `GID`) instead of the current user. `UID=0` implies UNIX superuser authority. Only a superuser can set these attributes. When a file is copied, these bits are turned off. When a file is moved, they are kept. When a file is written to, the extended attributes are removed; for setuid and setgid to be kept, the same authority is required as for turning them on in the first place.

Notes:

1. Strictly speaking, these UNIX reports show directory entries rather than files. In UNIX, the same file can have several path names known as hard links. The actual file is identified by an *inode* number, which is basically an index number within the Hierarchical File System. If there are several hard links to a file, the Authorized Programs report shows multiple directory entries for the file. Security is regulated at the inode level, but the effective file attributes also depend on the path name (hard link). Although a file can only be accessed with sufficient authority over the directories in its path, it is generally not prudent to rely on the security of a specific path being inaccessible, because of this link concept.

2. The CKFREEZE file used for these reports must include PDS directory information as well as UNIX file system information. This means that zSecure Collect must be run with the FOCUS=AUDITACF2 or FOCUS=AUDIT setting and UNIX=YES, preferably APF authorized (for completeness). If zSecure Collect is run unauthorized, you must specify PDS=YES and make sure that the program has sufficient access to all LNKLST concatenation and APF data sets. The UNIX ACL information is only available if zSecure Collect is run with UNIXACL=YES as well.

Auditing Authorized Programs

In a safe system, the security policy regarding the use of utilities that have the potential to bypass MVS, RACF, ACF2, or TSS protection mechanisms must be one of protection-by-default. Before permitting universal access to such utilities, you must perform a risk analysis.

In an MVS system, it can prove surprisingly difficult to determine the exact protection of AC=1 APF modules. For example, it is not uncommon that more than one module with the same name is available in the system. In addition, a number of questions must be answered to get a complete picture of the protection including the following:

1. Do the DATASET profiles covering the APF data sets containing the module have the attribute setting UACC(NONE) attribute.
2. Is the module covered by a PROGRAM profile in all data sets?
3. Does the PROGRAM profile have the attribute setting UACC(NONE)?
4. Is one of the APF data sets part of the LNKLST concatenation?
5. Which APF or non-APF authorized data set is the first in the LNKLST concatenation to contain the module?
6. Is the module present in the LPA?
7. Is the module present in the MLPA?
8. Is the data set covered by a global access table entry with an access level of READ or higher?
9. Is the data set profile in warning mode?

The TSOAUTH and LPAPROT reports have the same layout as the APFPROT report shown in Figure 237 on page 331 but exclusively show the TSO-authorized commands and LPA modules instead of all APF-authorized programs.

Figure 237 on page 331 shows a sample of the ISPF display panel for the Authorized programs report.

Figure 237. APF module protection overview panel

Table 178 lists the fields of interest for the APF module protection overview panel.

Table 178. APF module protection overview - field descriptions

Field	Description
Complex	The complex name for the security database.
System	The system name.
Timestamp	The date and time the information pertains to.
Count	The number of (entry points in) APF-authorized modules
Module	The name of an entry point in the module.
UACC	The consolidated universal access to the module, taking into account `PROGRAM` profile `UACC`, `DATASET` profile `UACC`, global access table, `LNKLST` concatenation residency, `LPA` residency, and warning mode. The UACC field can have the following values: *READLPA*. The data set `UACC` does not permit read access, but the module can be read in LPA. *LOADEXE*. The data set `UACC` does not permit read access, but the module can be run and read with the `LOAD` command. Running the `LOAD` command requires that you know the module name. *HIDDEN*. The module `UACC` is `NONE` because it is hidden by a module with the same name, concatenated in front of the `LPA` or `LNKLST` concatenation. *COPY*. The module can be read but not run. If its operation does not depend on APF authorization or library residence (`PADS`), all users can access its functionality by copying it to their own load library.

AuthAttr	The source of authorization for the module, which can be any of the following values: *AC=1*. Indicates permission to issue a `MODESET` command. *Bypass*. Bypass RACF and password security, from Program Property Table (PPT). *Key=n*. Alternate key (not key 8), from Program Property Table (PPT). *RACINIT*. RACINIT authority, from RACF authorized caller table ICHAUTAB. *RACLIST*. RACLIST authority, from RACF authorized caller table ICHAUTAB. *PADS*. Present on a conditional access list. *AuthPGM*. Can be called under TSO as an authorized program. *AuthCMD*. Can be called as TSO authorized command. *AuthTSF*. Can be called as authorized through the TSO service facility. *IEAAPP00*. I/O appendage authorized for use by non-APF users. **Note:** If the module has several sources of authorization, the `AuthAttr` column on the overview display panel only shows the first one. The list of authorization sources can be found on the detail display or by scrolling to the far right.

Member	PDS member name. This value differs from the module name in case the module has an alias name.
Datasetname	Contains the name of the data set containing the member. **** LPA **** indicates that the module was in the LPA but could not be found in any of the PDS directories. This value can also mean that the in-storage AC=1 attribute for the data set is different. **** module not found **** indicates that the module was not found in LPA or in any PDS (partitioned data set), but would have had special authorizations if present.
Volume	Volume serial containing the data set in the previous column.
x**LPA**	Identifies the LPA type: *P* for `PLPA`, *M* for `MLPA`, or *F* for `FLPA`. In addition, the sequence number in the LPA list concatenation of the data set is displayed.
h	Indicates that the module is hidden–not accessible through the `LPA` list or `LNKLST`. If applicable, this value (*h*) is listed between the **LPA** and **Lnk** columns.
Lnk	Contains the sequence number of the data set in the `LNKLST` concatenation. If the data set is not part of the `LNKLST` concatenation, the field is blank.
PROGRAM	This column contains the name of the program profile covering the module (if any).
PType	Indicates the mode of Program Control (z/OS V1R4 and up). Either blank, BASIC, or MAIN.

DATASET profile	Contains the name of the data set profile covering the data set. The value can be truncated if your line length is less than 153. In addition to the data set profile, this column can also include an entry from the global access table. The following columns are derived from the `AuthAttr` field: *AC1*. Can issue the `MODESET` command. *Byp*. Bypass RACF and password security, from `PPT`. *Key*. Alternate key (not key 8), from Program Property Table PPT. *Ini*. RACINIT authority–from the RACF authorized caller table ICHAUTAB. *Lst*. RACLIST authority–from the RACF authorized caller table `ICHAUTAB`. *PAD*. Present on a conditional access list. *PGM*. Can be started under TSO as an authorized program. *CMD*. Can be called as a TSO authorized command. *TSF*. Can be called as authorized through the TSO service facility. *APP* I/O appendage authorized for use by non-APF users.

You can select any module for a detail display by entering the **S** action character. To browse a module from the list, type the **B** action character in the entry field.

Tip: For an overview of the available actions, type the / action character in front of the module name.

Figure 238. Detail display of a module

When looking at UNIX files, the first thing to pay attention to is the file mode, which determines the access to the file in conjunction with the Access Control List (ACL). The file mode consists of three groups of access controls for the owning UID, for the owning GID, and for users that do not have an owning ID.

Each group is shown in three positions. The first position represents read access, the second write access, the third execute access. The third position can show the following additional user or group ID information:

- *s* or *S* for `setuid` (in the first group)
- *t* or *T* for the sticky bit property (in the third group).

A lowercase *s* or *t* indicates that the execute bit is on. The uppercase value indicates that execute bit is off.

For the files in these reports, make sure to inspect the global execute access, which is indicated by an *x* or *t* in the last position of the `FileMode` field. Also check the files to determine whether they have the correct privileges to begin with. You can examine other concerns, such as the protection of the file system where the files are stored, through the “SENSTRUS - Sensitive Data Trustees report” on page 317.

Note: If the UNIXPRIV class is active and RACLISTed, and the RESTRICTED.FILESYS.ACCESS resource is protected by a profile in that class, then RESTRICTED users are not granted access on the basis of the third ("other") group, unless they have a least READ access to the RESTRICTED.FILESYS.ACCESS resource.

The UNIX ACL contains the access permissions for additional users and groups, including *. The owning UID access bits take precedence over user entries on the ACL, which take precedence over any group entries. The owning GID and additional group entries on the ACL have the same precedence, and access given by any of them is granted. Only if none of these apply, the third ("other") group is checked.

A sample UNIXAPF display is shown in the following figure.

```

****************************** BOTTOM OF DATA ********************************
```

Field	Description
Pri	The audit priority for this file

Field	Description
T	The type of file: regular file (-), block special file (b), character special file (c), directory (d), external symlink (e), symlink (l), pipe or FIFO (p), socket (s).
FileMode	The effective file mode, shown as lists of permissions for specific groups. The groups are owner (u), group (g), and other (o). When the permissions of all groups are equal, an (a) is used. The permissions can be read (r), write (w), execute (x), setuid/setgid (s), and sticky bit (t). The setuid/setgid and sticky bits indicators are shown in uppercase (S/T) when execute permission is off. Note that this format is the same as used by the chmod command.
+	Whether this file has any of the following extended ACL entries: access, directory default, or file default.
apsl	The effective extended attributes, shown as a list of attributes that are on (+) and a list of attributes that are off (-). Possible attributes are APF authorization (a), program controlled (p), address space sharing (s), and library sharing (l).
AuF	The combined audit flags: three positions for read, write, and execute access, each specifying **s** for successes, **f** for failures, **a** for all, or **-** for none. "Combined" means that either the owner or an auditor has requested auditing.
Owner	The RACF `userid` that is mapped to the owning uid. If there are several such RACF userids, this is the alphabetically first one.
Group	The RACF group that is mapped to the owning gid. If there are several such RACF groups, this is the alphabetically first one.
Relative pathname (within FS)	Path name relative to the file system's mount point.

Select any file for a detail display. You can browse the regular files in the displayed list by entering the **b** action character.

Figure 239. UNIX files with APF authorization

The display is divided into three sections. The first section shows the effective settings. For example, the absolute pathname consists of the relative pathname within the HFS or zFS data set, prefixed by the mount point of the file system. The effective flags take the mount attributes and mode into account. The second section shows the physical characteristics, such as the flags actually indicated in the file system itself. The third section shows the UNIX access lists. An access ACL can be shown for any file type. For a directory, a directory default and a file default ACL can be shown as well.

By entering the action character **B** in front of the ABSOLUTE PATHNAME in the displayed panel, it is possible to browse the contents of the file.

The system view contains the following fields.

Table 179. UNIX file detail display - System view of file fields

Field	Description
Complex name	The complex name for the security database
Sysplex name	The sysplex name.
System name	The system name.
Absolute pathname	The full path name for the file.
FS mounted with SECURITY	Whether the file system is mounted with the SECURITY attribute. If not, any user can access and change any file in it.
FS mounted with SETUID	Whether the file system is mounted with the `SETUID` attribute. The following attributes are only honored if this attribute is set: setuid, setgid, APF, and program control attributes.
FS mounted READ/WRITE	The mode in which the file system is mounted. The mode can be either of the following values: • *READ* The file system is mounted read-only. • *RDWR* The file system is mounted with read and write access.
File access attributes	The effective file mode, shown as lists of permissions for specific groups. The groups are shown using the following values: *u* for owner, *g* for group, *o* for other, or *a* or all. The permissions can be *r* read, *w* write, *e* execute, *s* setuid or setgid, and for sticky bit setuid is indicated by the value *u*; setgid is indicated by the value *g*.
Security label	The file security label.
Extended file attributes	The effective extended attribute. The + symbol indicates an active attribute; the - symbol indicates an inactive attribute.
Effective audit flags	The effective audit flags. Flags are listed as successes (*s*) and failures (*f*) for each of the following access types: *r* read, *w* write, and *e* execute. If the access type does not matter, the flags are listed in a single list.
Owner name	The RACF `userid` that maps to the file uid. If there are more such users, a list is shown.
Group name	The RACF group that maps to the file gid. If there are more such groups, a list is shown.
Device	The device number identifying the mount point.
Relative audit priority	The audit priority for this file.
Audit concern	The audit concerns identified for this file. The audit concerns that can be identified can be found in "UNIX: UNIX System Services File System" on page 1480.

The display contains the following physical file attributes.

Table 180. UNIX file detail display - Physical file attributes fields

Field	Description
Complex that owns file system	Complex of the system that owns the file system.
System that owns file system	System that owns the file system.
File system data set name	The name of the data set that holds the file system.

Table 180. UNIX file detail display - Physical file attributes fields (continued)

Field	Description
Volume serial for file system	The volume serial of the HFS or zFS data set.
File system DASD serial + id	Manufacturer/Factory/Serial identifying the DASD, and device tag id (port) assigned to this volume on the owning system.
Relative pathname within FS	Path name relative to the file system's mount point.
File type	Indicates the UNIX file type which can have any of the following values: • - regular file • *p* pipe (or FIFO) • *d* directory • *b* block special file • *e*external symlink • *s*socket • *c* character special file • *l* symlink.
Physical access attributes	The physical file mode, shown as lists of permissions for specific groups. The groups are shown as *u* for owner, *g* for group, *o* for other, or *a* or all. The permissions can be *r* read, *w* write, *e* execute, *s* setuid or setgid, and sticky bit (setuid is indicated by the value *u*; setgid is indicated by the value *g*).
Physical extended attributes	The physical extended attributes, shown as a list of attributes that are on (+) followed by a list of attributes that are off (-).
User-requested audit flags	The audit flags requested by the owner, shown as lists of Flags are listed as successes (*s*) and failures (*f*) for each of the following access types: *r* read, *w* write, and *e* execute. If the access type does not matter, the flags are listed in a single list.
Auditor-specified audit flags	The audit flags specified by the auditor, shown similarly.
User id	The user ID for the file.
Group id	The group ID for the file.
Inode number	The inode number which identifies the file within the file system.
File audit id	The ID for the auditor.
Number of hard links	The number of directory entries for the file. A UNIX file has no canonical path name. The inode identifies a file within the file system. File attributes and other information is associated with the inode, not the path name.

The UNIX access control list contains the following fields.

Table 181. UNIX file detail display - Access control list fields

Field	Description
User	The user ID to which the entry pertains. This field can also contain the following values: • *-group-* shows up for an unexpanded ACL or an exploded ACL for an empty group when the **ACL id** field shows the group. • *-undef-* indicates that the user ID or group ID in an unexpanded or exploded ACL does not correspond to an existing RACF ID. • *-any-* indicates a global access setting.
TOrwx	The ACL Type. The value can be any of the following: • ACL type: *d* directory default, *f* file default, blank for access. • ACL entry Origin: *u* owning user, *g* owning group, *o* other, + ACL entry, or *a* Auditor attribute. • Access permissions indicate if the ID has authority to read (*r*), write (*w*), or execute (*x*).
ACL id	A RACF user or group associated with the UID/GID. This column can show a RACF user or group, or any of the following special origin values: • *-group-* for an owning group GID. • *-other-* for the global access setting. • *-any-* indicates any user. • *-owner-* for a file owner UID. • *-ACLuid-* for a UID on the ACL. • *-ACLgid-* for a GID on the ACL. • *-audit-* for directory read/execute access through the system-wide AUDITOR attribute. • *-more-* when an actual access level has more than one origin.

Table 181. UNIX file detail display - Access control list fields (continued)

Field	Description
UID/GID	The UID or GID that grants this access, or an indication why none applies. This value represents a UID if the value is a number, a RACF identity was determined, and the ACL ID contains either *-owner-* or *-ACLuid-*. Otherwise, the value represents a GID. This column can also contain the following special values: • *n/a* for the global access setting. • *-any-* for the user owner. • *-more-* for a composite entry or when read, write, and execute access to a directory is granted to a user on the basis of the RACF auditor attribute. For an exploded ACL, this field can have one of the following values: • *-no uid-* when there is no associated UID, either directly or through the BPX.DEFAULT.USER. • *-no gid-* when there is no associated GID.
Name	The user name.
InstData	The installation data for the user or group.

The layout of the UNIXCTL report on program controlled files is identical to that of the UNIXAPF report. The UNIXSUID and UNIXSGID report are the same as well, except that they have a few extra summary levels. Figure 240 shows a sample of the UNIXSUID report.

Figure 240. UNIX files with SETUID authorization

The display contains the following fields of interest.

Field	Description
Pri	The highest audit priority for any audit concern for the system.
Complex	The complex name for the security database.
System	The system name.
Setuid files	The number of setuid files in the system.

Field	Description
Pri	The highest priority for files that switch to this identity.
Running under uid	The identity the file switches to.
Setuid files	The number of files that run under this identity.
Pri	The highest audit priority for any audit concern for a mount point.
Setuid files	The number of setuid files in the file system.
FS mount point	The directory at which the file system is mounted.
Pri	The audit priority for this file.
T	The file type.
FileMode	The effective file mode.
+	Indicates if this file has any of the following types of extended ACL entries: access, directory default, or file default.
apsl	The effective extended attributes.
AuF	The combined audit flags.
Owner	The RACF user ID that is mapped to the owning UID. If there are several such RACF `userids`, this is the alphabetically first one.
Group	The RACF group that is mapped to the owning GID. If there are several such RACF groups, this is the alphabetically first one.
Relative pathname (within FS)	Path name relative to the file system's mount point.

PADS - Program Access to Data Sets report

The display shows the protection of load modules that can be used for Program Access to Data Sets (PADS). These load modules are covered by program profiles present on the conditional access list of a DATASET profile. Usually, they give more access to the data set than the normal access list would grant.

Background

The report includes the highest access to arbitrary users as given by the combined action of PROGRAM profile UACC, DATASET profile UACC, LNKLST concatenation residency, LPA residency, global access table, and profile warning mode. In addition it shows all module occurrences with LNKLST concatenation and LPA list concatenation numbers, MLPA residency in-storage, base member names for alias entries, the authorizing attributes, attributes extending the authorization to the TSO environment (AuthCMD AuthPGM AuthTSF), and the RACF profile member names.

A CKFREEZE file is required. It must include PDS directory information for this function. This means that zSecure Collect must either be run APF-authorized with FOCUS=RACF or non-APF authorized with FOCUS=RACF,PDS=YES and sufficient access on all LNKLST concatenation and APF data set directories.

Note: This report does not treat all systems equally, so be careful about multiple input sets.

You can specify a minimum universal access level of interest for entries to be included in the report, as well as the system to be used as the primary viewpoint for the reports. If you use the ISPF STATUS AUDIT menu, you are automatically prompted with a customization panel where you can fill in the desired access level and SMF id of the desired primary system. In a batch run, include the CARLa commands REPORT ACCESS=level or DEFAULT SYSTEM=smf_id, respectively.

The meaningful access levels that can be specified are shown in the following table.

Level	Meaning
ALTER	ALTER access.
CONTROL	CONTROL access.
UPDATE	UPDATE access.
READ	READ access.
READLPA	The UACC does not permit READ access, but the module can be read in the LPA.
LOADEXE	The UACC does not permit READ access, but the module can be executed and read using LOAD.
EXECUTE	Execute access.
COPY	A module can be read, but not executed. If the operation does not depend on APF or library residence, then anyone can access its functionality by copying it to his or her own load library.
HIDDEN	A PDS member or load module hidden by a similarly named member in a library in front of this library.

Auditing Program Access to Data Sets

In a safe system, the security policy regarding the use of utilities that have the potential to grant special access to data sets must be one of protection-by-default. Update authority to libraries with such utilities must be tightly controlled. Universal access to these utilities must only be granted after performing a risk analysis.

In an MVS system, it can prove surprisingly difficult to determine the exact protection of program modules. For instance, it is not uncommon that more than one module with the same name is available in the system. In addition, a number of questions need to be answered to get a full picture of the protection for modules. These questions are:

1. Do the DATASET profiles covering the APF data sets containing the module have UACC(NONE) ?
2. Is the module covered by a PROGRAM profile in all data sets?
3. Does the PROGRAM profile have UACC(NONE)?
4. Is one of the APF data sets part of the LNKLST concatenation?
5. Which (APF or non-APF) data set is the first in the LNKLST concatenation to contain the module?
6. Is the module present in LPA?
7. Is the module present in MLPA?

8. Is the data set covered by a global access table entry with READ or higher?
9. Is the data set profile in warning mode?

The layout of the report is identical to that of the APFPROT report which is described in "APFPROT - Authorized Programs reports" on page 328.

STCPROT - Started Task protection report

This report shows the authority and protection defined for started tasks. The report combines information from the following sources:

- Started Procedure Table ICHRIN03
- RACF database
- JES2/JES3 proclib library concatenation in use for started tasks
- Procedure library used by the master address space (MSTR subsystem)

Note: If you are interested in the STARTED class and the Started Procedure Table rather than the protection of the started tasks, look at the STCTABLE report in "STCTABLE - Started Procedure Table and Started Class" on page 288.

Background

Started tasks are called by means of the START operator command, optionally with a SUB= parameter to indicate a target subsystem. The default subsystem is the primary subsystem, usually JES2 or JES3. Security zSecure supports both JES2 and JES3 as the primary subsystem, and in addition it supports the MSTR subsystem that is present in every MVS system.

It is important to curb access to the STC proclibs, because the JCL for started tasks with system authorization can be added or modified, and activated with a MVS START command without knowing the password of the authorized user.

Depending on the PTF level and RACF database level, a started procedure that is revoked might still run. However, it runs with reduced with reduced functionality which can result in problems submitting batch jobs, allocating new SMS-managed data sets, or obtaining printed output.

The consistency between ICHRIN03, the RACF database, and the JES2/JES3 proclibs can be verified with VERIFY STC (see "Finding inconsistencies in started task definitions" on page 367).

A `CKFREEZE` file is required to generate the report. The file must have been created with an authorized run of zSecure Collect. If you use `CKFREEZE` data collected during an unauthorized run with FOCUS=RACF,PDS=YES, this function only reports on the MSTR proclib without including information about the JES procedure libraries.

Note: This report does not treat all systems equally, so be careful about multiple input sets.

You can specify a different sort order, a minimum universal access level to select the entries to be included in the report, as well as system to be used as the primary viewpoint for the reports. In addition, you can exclude entries for undefined started task user IDs.

If you use the STATUS AUDIT menu, you are automatically prompted with a customization panel where you can specify these options. You can also customize and create the report in a batch process by using the CARLa commands listed in Table 182.

Table 182. Started Task protection report - CARLa command statements for generating the report

Reporting option	CARLa
Select a default system	DEFAULT SYSTEM=smf_id
Sort by member	REPORT BY=MEMBER
Exclude undefined userids	SUPPRESS ID=* ID=++++++++
Specify minimum UACC	REPORT ACCESS=level

You can specify any of the access levels listed in Table 183.

Table 183. Valid Access Levels for customizing the Started Task protection report

Level	Meaning
ALTER	ALTER access.
CONTROL	CONTROL access.
UPDATE	UPDATE access.
READ	READ access.
READLPA	The `UACC` does not grant `READ` access, but the module can be read in the LPA.
LOADEXE	The `UACC` does not permit `READ` access, but the module can be executed and read using LOAD.
EXECUTE	Execute access.
COPY	A module can be read, but not executed. If the operation does not depend on APF or library residence, then anyone can access its functionality by copying it to his or her own load library.
HIDDEN	A PDS member or load module hidden by a similarly named member in a library in front of this library.

Auditing Started Task Protection

Figure 241 on page 346 shows the overview panel for the Started Task Protection report.

Figure 241. Started Task protection report - overview panel

The summary line at the top shows the complex name (which database) and system name with time stamp, and the number of started procedures for this complex. When multiple complexes are connected, you first have to select a complex to see this overview.

The display contains the following fields of interest.

Table 184. Started Task Protection report overview panel - field descriptions

Field	Description
Complex	The complex name for the security database.
System	The SMF system ID. Each system can have its own Started Procedure Table ICHRIN03, even while sharing the RACF database.
Timestamp	The time stamp of the database or unload used.
Count	The number of started task entries shown.
Procname	The name of the procedure JCL member in the procedure library. This name is used on the START command to start the task.
Userid	The `userid` assigned by a STARTED profile. This column can contain *, which is the default RACF user ID for a task originating from within the system. Issue the SUPPRESS ID=* to suppress these report lines. For an invalid STARTED profile, this column can contain the JES user ID *undefined*' user, by default ++++++++.

Table 184. Started Task Protection report overview panel - field descriptions (continued)

Flags	Special authorizations or conditions for the started task, coming from the RACF user profile or from the STARTED profile. A character can be displayed at a specific column. Possible characters are: * . An unusual condition exists for this task, a mismatch in a table or database for example. Use the VERIFY STC command to troubleshoot the problem. *r*. The user assigned to the started procedure is revoked. Depending on your RACF and PTF level, the task either cannot be started because it is revoked, or it is running with reduced functionality. *s*. System-wide SPECIAL authority. *o*. System-wide OPERATIONS authority. *a*. System-wide AUDITOR authority. *p* The task is privileged, which means that all RACHECKs are permitted without an audit trail. *t*. The task is trusted, which means that all RACHECKs are permitted but with an audit trail. *D*. The current connect group is the user's default group. *S*. The procedure uses a RACF STARTED profile. *3*. The procedure uses ICHRIN03. *u*. The started task user ID is unprotected, so it can be used to log onto the system.
Group	The current connect group that is used if the task is started.
Subs	The subsystem name the output line applies to. The START command can be issued with this subsystem name in the SUB= parameter. The SUB= parameter is required to direct the START command to a subsystem other than the default (primary) subsystem.
Lib	The sequence number of the procedure library in the concatenation. Each subsystem on each system can have its own concatenation.
h	Indicates that a JCL member is hidden by a member with the same name in a procedure library in front of this library. When the Subs column indicates +, the detail display shows for which subsystem(s) the member is hidden.
Last updt	The last modification date in the ISPF statistics of the JCL member.
By	The user ID present in the ISPF statistics of the JCL member.
STARTED profile	The RACF STARTED profile, if one is found.
UACC	The consolidated universal access of the procedure library. This takes into account the data set profile, the warning mode, the global access table, and the PROTECTALL setting.
Volume	The DASD volume serial where the procedure library resides.

Table 184. Started Task Protection report overview panel - field descriptions (continued)

Dataset	The data set name of the procedure library containing the JCL member for the started task.

If more than one value applies, the **Subs Lib** columns shows + +. The applicable values are listed on the detail display.

Table 185 lists the available action commands.

Table 185. Started Task Protection panel - Available action commands

Command	Description
B - Browse proclib member	Browse the selected procedure using the ISPF BROWSE service.
L - RACF listuser command	Generates a RACF `LISTUSER` command for the STC user ID. Results are presented in a temporary file that you can navigate through using scroll keys or find commands. The default RACF user `*` and the undefined user `++++++++` cannot be listed.
S - Show additional information	Shows additional information for the started procedure. The extra information can include subsystem names, whether the member is hidden by a member with the same name in a procedure library, and the sequence number of the procedure library in the proclib concatenation.
V - View proclib member	View the selected procedure using the ISPF VIEW service.

GLBW - Globally writable data reports

These reports show the z/OS data sets and z/OS UNIX files (zSecure Audit for ACF2 only) that can be updated by almost any user. The GLBWDSN report shows the data sets that are vulnerable to trojan horse and backdoor attacks. The GLBWUNIX report is a UNIX equivalent of the same report.

Background

Hackers often exploit files that can be updated by anybody to increase their authority. For example, they change an executable, source, or parameter file in the hope that it is used by a user with more authority than their current, possibly stolen user ID. This is called a trojan horse attack.

The trojan horse can give the stolen user ID more authority, or change yet another program to install a back door that grants access to the hacker even after the global write condition has been removed.

Globally writable UNIX directories are also a prime way to spread viruses. Countermeasures to protect the UNIX environment are to limit globally writable files so that only well understood applications like `/var` and `/man` are globally writable and to make sure that authorized users for the current directory do not have globally writable files in their search path.

Auditing globally writable data

Figure 242 on page 349 shows a sample GLBWDSN display panel with information about data sets vulnerable to trojan horse and back door attacks.

Figure 242. Auditing globally writable data - Data set vulnerability report

Table 186 list the fields of interest in for the Data set vulnerability report.

Table 186. Auditing globally writable data - Data set vulnerability report

Field	Description
Complex	The complex name for the security data sources.
Timestamp	The date and time to which the information pertains
Profiles	The number of profiles for which information is available
HighAcc	The highest general access found
Profile key / data set name	The profile reported on
Volume	Volume serial (for a discrete profile)
Access	The access level any user has.
Via	List the reason that access is granted. The value can be any of the following: • Access list entry • *-UACC-* (Universal access level) • *-WARN-* (Profile in warning mode) • *-UNPROT-* (No profile and no protection by default)
When	If the data set has conditional access, the class and resource name are required.

Select any profile to see what resources it protects.

```

The display contains the following fields of interest.

Field	Description
Type	Profile type: • *GENERIC* • *VSAM* • *NONVSAM* • *MODEL* • *TAPE* • *missing* (Indicates that data sets are not protected.)lowercase shows data • *lowercase* (Shows data set resources. For more information, see the table in "SENSPROF - Sensitive Data by Profile report" on page 321).
Profile key / Data set name	Profile key, optionally followed by names of data sets covered by this profile.
Volume	For a discrete profile, the volume serial of the data set.

For UNIX, global write access is of special interest for the following types of files:

- Files with APF, SETUID, or SETGID authorization.
- Files that run program controlled.
- Some special (configuration) files and directories.
- Files that serve a specific function for a user, a profile for example.
- User home directories.

When you configure this option, verify that /tmp variable has the sticky bit on for protection against removal of file and directories owned by other user IDs. For a list of the possible audit concerns, see “UNIX: UNIX System Services File System” on page 1480.

A sample GLBWUNIX display is shown in the following figure.

```

The display contains the following fields of interest:

Field	Description
Files	The number of occurrences of this UID in this file system
FS mount point	The mount point.
T	The file type.
FileMode	The effective file mode
apsl	The effective extended attributes.

Field	Description
AuF	The combined audit files.
Group	The group that is associated with this file.
Relative pathname (within FS)	The relative path name for this file from the mount point of the file system.

The layout of the detail report is identical to that of the UNIX reports for authorized files. See "APFPROT - Authorized Programs reports" on page 328.

Auditing undefined GIDs

The GIDNOGRP report is virtually identical to the UIDNOUSR report described in "UIDNOUSR - UNIX ids used in the file system, but not defined to RACF" on page 352. Only UID and GID, and owner and group are exchanged for each other.

AU.V VERIFY - Verify Selection List

The `VERIFY` command is described in "VERIFY" on page 942. It combines profile data with resource descriptions, and reports on inconsistencies. `VERIFY` also generates commands to fix some inconsistencies. If a `CKFREEZE` is present, `VERIFY PERMIT` supports resource deletion, which means that the data sets covered by a profile that is removed are themselves removed as well.

You can use any number of `VERIFY` selections in one run, or select just one, by selecting the fields as shown in Figure 243. All but the first few selections require a `CKFREEZE` file.

```
  Menu  Options  Info  Commands  Setup          StartPanel
------------------------------------------------------------------------------
                        zSecure Suite - Audit - Verify
Command ===> ____________________________________________________________

Enter "/" to select one or more options
_  Permit            Find undefined users and groups and their profiles

_  User permit       Find and remove redundant permits to userids
_  Connect           Compare USER, GROUP and CONNECT profiles
_  PADS              Programs on conditional access list have PROGRAM profile
_  Group tree        Loops in grouptree
_  Password          Userids with trivial passwords (not from an unloaded db)
_  Protect all       All datasets are protected by a (discr or gen) profile
_  On volume         Datasets defined by discrete profiles actually exist
_  Not empty         Generic profile has matching disk or tape datasets
_  All not empty     As above, even 'outer' generic profiles
_  Indicated         Discrete profile exists for RACF-indicated datasets
_  Program           Datasets as members in PROGRAM profile exist on disk
_  Pgm exists        PROGRAM profiles cover actual load modules
_  Started task      Check that procedures can indeed be started, etc.
_  TSO all RACF      All TSO users should have RACF password and TSO segment
_  Sensitive         Sensitive datasets not protected properly
_
```

Figure 243. Audit Verify Command

The verify option selection panel is followed by customization panels. You can use the first panel shown in Figure 244 on page 354 to change the output sort order and to suppress output that you do not want to include in the report.

```
  Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                        zSecure Suite Verify
Option  ===> ____________________________________________________________

Complete any of the selection criteria below and press ENTER
Enter "/" to select sort option
  _  Message        - Sort output lines by message type (default)
  _  Volume         - Sort output lines by volume serial and dataset name
  _  Dsname         - Sort output lines by dataset name
  _  Program        - Sort output lines by program name (AC1, PADS and STC

  _  Suppress FALLBACK (do not flag unused ICHRIN03 entries)
  _  Simulate program control mode . . ENHWARN     (BASIC,ENHANCED or ENHWARN)

Limit amount of output
 Message limit  . . 50______     Message limit per volume
 Suppress msg (4 digit message numbers to ignore, separated by commas)
                    ____________________________________________________
 Suppress vol (messages for these disk volumes can be ignored)
                    ______ ______ ______ ______ ______ ______ ______ ______
 Suppress id (userids to be suppressed (e.g. * and ++++++++))
                    ________ ________ ________ ________ ________ ________
```

Figure 244. Verify - customize sort order and suppress output

The sort options are mutually exclusive. The SUPPRESS FALLBACK option applies only to VERIFY STARTED TASK; it means that entries in Started Procedure Table ICHRIN03 are only taken into consideration if there is no overriding profile in the STARTED class for a started task.

The other suppress options should be self-explanatory.

You can use the **Simulate program control mode** to simulate the mode in which RACF program control runs (z/OS 1.4 and up). This option applies only to VERIFY PADS. Note that * and +++++++ are the default user IDs under which a started task can be run when there is no ICHRIN03 or STARTED match, respectively.

A subsequent panel might open asking you whether data sets and ID-specific general resource profiles are to be removed if the ID does not exist anymore. You can also specify up to 8 classes to be excluded from processing.

```
  Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                        zSecure Suite Verify
Option  ===> ____________________________________________________________

Delete profiles as well as datasets when removing undefined ids?

Common RACF problems

The standard RACF product includes utilities and commands to handle most of the situations which security administrators, auditors, and technical staff are likely to encounter. However, some of these facilities are difficult to use or take too long to consider using them on a daily basis. As a result of this, some installations have been forced to develop their own procedures for dealing with these situations and others have been unable to afford the resources to deal with them on a regular basis.

This section of the manual shows how Security zSecure can be used to provide fast solutions to some of the most common problems facing RACF users today in four major areas:

USER/GROUP Maintenance

- Finding user/group/connect inconsistencies (ensures USER, GROUP, and CONNECT profiles in synchronization)

PROGRAM Class Maintenance

- Checking for obsolete conditional access lists (when PROGRAM profiles have been removed)
- Checking for program/data set referential integrity (finds non-existent data set/volume PROGRAM combinations)
- Checking for program/load module referential integrity (finds PROGRAM profiles not describing any physical module)

DATASET Maintenance

- Finding and protecting unprotected data sets (checks for possible unrecorded access depending on the current PROTECTALL setting)
- Removing unused discrete profiles (resulting from volume-level operations)
- Finding and removing redundant discrete profiles (after conversion from ADSP to generic environment)

- Removing unused generic profiles (after deletion of 'subject' data sets)
- Converting to generic profiles (Security zSecure commands to assist in conversion to generics)
- Finding and resetting unnecessary RACF-indicated bits (where no discrete profile exists)

STARTED Class Maintenance

- Finding inconsistencies in started task definitions.

Checking for obsolete conditional access lists

RACF offers the possibility to grant access to data sets only through specific programs. This facility is called Program Access to Data Sets (PADS). This is done by having an extra access list on the data set profile called the *conditional access list*. The conditional access list consists of entries containing an *id*, an *access level*, and a *program name*. For the entry to be effective, the program name must be defined as a profile in the class PROGRAM, and the user must call the program from a 'clean' environment.

The problem is that no check is made by RACF on the existence of the PROGRAM profile, neither when setting the conditional permit, nor when deleting a PROGRAM profile. Most users have discovered this by trying to debug 913 abends for PADS data sets, e.g. due to a typing error in the program name on the conditional access list. A more serious problem is introduced if the PROGRAM profiles (and presumably the programs, too) are removed from the system. A conditional access list entry then exists that serves no function anymore, a so-called *obsolete conditional access list entry*.

Depending on the procedures around the use of the PROGRAM class, this can result in a *security exposure*. The exposure exists because a data set profile gives access based on a program name that is undefined. Anybody with class authorization for PROGRAM can define the program profile, indicating a program in his own load library. He then has access to somebody else's data set.

Security zSecure provides a function specifically designed to report and remove obsolete conditional access list entries. The report is created by means of the following command (option **AU.V**):

```
VERIFY PADS
```

Figure 249 gives an example of the relevant parts of the output. Note that the query also specifies a global exclude of the catch all profiles * and ** (via SETUP PREAMBLE), because in a database with such catchalls no output would otherwise have been generated! Messages displayed depend on the program security mode.

```
Include CKRALLOC (ISPF variable)
    2 |/* Data from DD070525 */
    3 |alloc type=UNLOAD dsn='SYSAPPL.CNRACF.DD070525.UNLOAD'  complex=DD070525
    4 |
    5 |alloc type=CKRCMD DD=CKR02CMD
End of  CKRALLOC (include level 1)

Include CKRCMDV  (ISPF variable)
    1 |VERIFY PADS
End of  CKRCMDV  (include level 1)

CKR1204 04 No specific program profile found for program PROGRAM1 used in dataset profile C##BSG1.E307011.TEST
```

Figure 249. Sample VERIFY PADS output

To generate commands to remove the obsolete entries, the CKRCMD file must be allocated.

The commands generated can be longer than 72 characters. You can use the default CLIST format (VB 255).

Checking for program existence

Profiles in the class PROGRAM can contain data set name/volume combinations as members. RACF does not check on the existence of these data sets, either during profile creation, or during data set deletion. This can easily lead to superfluous and inconsistent database entries.

One type of inconsistency can occur if a load library is moved to another volume, by SMS for example. If the library is no longer listed in a `PROGRAM` profile because of its new volume, 913 abends occur when using Program Access to Data Sets (PADS) with this program from this library.

In addition, a *security exposure* results if the program-protected library is part of the Authorized Program Facility (APF). It is common procedure to protect sensitive utilities in the MVS LNKLST concatenation with PROGRAM profiles. Utilities can be considered *sensitive* if they have the ability to circumvent RACF. To have this potential, utilities must be part of an APF library and linked with AC=1. Now if the APF library containing the sensitive utility is moved to another volume, then access to its function is not restricted anymore based on the access list of a PROGRAM profile, unless the PROGRAM profile is updated to contain the new volume.

Security zSecure provides a function designed to report and remove data set/volume combinations that do not exist or are otherwise invalid (data set is not partitioned, volume is not mounted or is not a z/OS readable disk). It also provides a function designed to report and remove PROGRAM profiles that are not actually protecting any program in any data set. Note that for the APF problem described above, removal of the old combination is not enough - the new combination should be added as well.

If you have allocated a CKRCMD file, RACF commands to remove the invalid PROGRAM profiles and members are generated. Because commands can be longer than 72 characters, use the default CLIST format (VB 255).

Before running the generated commands, review them to make sure that the results are what you intended. The analysis that leads to the generation of REMOVE or DELMEM commands is primarily focused on security. Executing the commands blindly can lead to availability problems. The correct remedy might be restoring datasets instead of removing the profiles or members. When in doubt, consult your systems programmer.

The following CARLa command (found in the interactive interface as AU.V - Program) checks the validity of the specified PROGRAM profile members:

```
VERIFY PROGRAM
```

This function requires a CKFREEZE file.

Figure 250 on page 359 gives an example of the relevant parts of the SYSPRINT from running this command:

```
Include CKRALLOC (ISPF variable)
    2 |/* Data from DD070525 */
    3 |alloc type=UNLOAD dsn='SYSAPPL.CNRACF.DD070525.UNLOAD'  complex=DD070525
    4 |
    6 |alloc type=CKFREEZE dsn='SYSAPPL.CNRACF.DD070525.CKFREEZE'  complex=DD070525
    7 |
    9 |alloc type=CKRCMD DD=CKR02CMD
End of  CKRALLOC (include level 1)

Include CKRCMDV  (ISPF variable)
    1 |VERIFY PROGRAM
End of  CKRCMDV  (include level 1)

```

Figure 250. Sample VERIFY PROGRAM output

VERIFY PROGRAM can issue messages indicating why a member could be removed from a PROGRAM profile, or that information is missing to decide on that. There are several messages for indicating the various conditions. VERIFY PROGRAM also flags volume-specific members that are made redundant by a member without a volume specification. If the messages indicate that information is missing, you should investigate why, solve the problem(s) and rerun VERIFY PROGRAM. See also “VERIFY PROGRAM, PGM” on page 950.

The following CARLa command (found in the interactive interface as AU.V - Pgm exists) checks the existence of load modules in the libraries indicated by the PROGRAMprofile members:

```
VERIFY PGMEXIST
```

This function requires a CKFREEZE file.

Figure 251 gives an example of the relevant parts of the SYSPRINT from running this command:

```
Include CKRALLOC (ISPF variable)
    2 |/* Data from DD070525 */
    3 |alloc type=UNLOAD dsn='SYSAPPL.CNRACF.DD070525.UNLOAD'  complex=DD070525
    4 |
    6 |alloc type=CKFREEZE dsn='SYSAPPL.CNRACF.DD070525.CKFREEZE'  complex=DD070525
    7 |
    9 |alloc type=CKRCMD DD=CKR02CMD
End of  CKRALLOC (include level 1)

Include CKRCMDV  (ISPF variable)
    1 |VERIFY PGMEXIST
End of  CKRCMDV  (include level 1)

-------------------------------------------------------------------------------------------------------------------------------
M E S S A G E S   V E R I F Y   P G M E X I S T         25 Mar 2007 00:05                                                page 5

CKR0296 04 PROGRAM profile w/o load module but info missing  C##4     RACTRACE
           PDS directory not in CKFREEZE for data set   C##4                    M95DR2 SYS1.C##.LINKLIB
CKR0297 04 Obsolete PROGRAM, load module not in libraries    TEST     ABEND806
```

Figure 251. Sample VERIFY PGMEXIST output

VERIFY PGMEXIST can issue messages CKR0296 and CKR0297. The former indicates that the PROGRAM profile does not protect any load module (and generates a command to remove the profile). The latter indicates that the PROGRAM profile does not seem to protect any load module, but some information necessary to conclude that is missing. In this case, a command to remove the PROGRAM profile is generated, but it is commented out. You should investigate why the indicated information is missing, solve the problem(s) and rerun VERIFY PGMEXIST. See also “VERIFY PGMEXIST, PROGRAMNONEMPTY, PROGRAMNOTEMPTY, PGMNONEMPTY, PGMNOTEMPTY” on page 949.

Finding and protecting unprotected data sets

It is possible that data sets exist in the system that are not matched by any profile in RACF. If the RACF indicated bit of these data sets is off, access to the data sets is governed by the setting of the system-wide RACF option PROTECTALL. (Data sets with their RACF indicated bit on are discussed in Finding and resetting unnecessary RACF indicated bits).

If PROTECTALL(FAIL) is active, access is only granted to user IDs with SPECIAL authority and for user IDs equal to the first qualifier of the data set name. We call these data sets *inaccessible* data sets. If PROTECTALL(FAIL) is not active, access is granted to any user ID, even for user IDs not defined to RACF. We call these data sets *unprotected*. If the RACF indicated bit is on and no generic or discrete profile is found matching the data set, RACF denies all access which makes these data sets inaccessible.

In all cases, it is useful to identify the data sets not protected by any profile. In a PROTECTALL environment, a data set might be unprotected because a generic profile was removed prematurely without first deleting or renaming the data sets. In a non-PROTECTALL environment, data sets might be unprotected even though your standards dictate protection.

Security zSecure provides a function to identify all data sets without generic or discrete profiles. This function is requested by selecting option **AU.V**, Protect all, or by issuing the following command.

```
VERIFY PROTECTALL
```

If a RACF indicated data set has no discrete or matching generic profile, Security zSecure generate commands to create discrete profiles for these data sets. However, most of the time you might not want to create discrete profiles. It is better to define a generic profile and configure PERMITs for the groups requiring access. Generated commands are written to the `CKRCMD` file.

A `CKFREEZE` file is required for this function.

Figure 252 gives an example of the relevant parts of the SYSPRINT from running this command:

```
Include CKRALLOC (ISPF variable)
     2 |/* Data from DD070525 */
     3 |alloc type=UNLOAD dsn='SYSAPPL.CNRACF.DD070525.UNLOAD'  complex=DD070525
     4 |
     6 |alloc type=CKFREEZE dsn='SYSAPPL.CNRACF.DD070525.CKFREEZE'  complex=DD070525
     7 |
     9 |alloc type=CKRCMD DD=CKR02CMD
 End of  CKRALLOC (include level 1)

 Include CKRCMDV  (ISPF variable)
     1 |VERIFY PROTECTALL
 End of  CKRCMDV  (include level 1)

Figure 252. Sample VERIFY PROTECTALL output

Note that the error messages on data set level are preceded by summary messages per volume. You can modify the order of the messages by means of the BY parameter of VERIFY. See “VERIFY” on page 942.

The present version of the product does not support this verification for data sets that are only known to CA1, RMM, and TLMS.

If Automatic Backup and Recovery (ABR) is used with the PROFKEEP option, a discrete profile for a migrated non-VSAM data set is assumed to protect it. This assumption is incorrect if the data set does not have the RACF indicated bit on; to verify whether this is the case, however, would necessitate investigating the migration copy, to which end all the migration (DASD and) tapes would have to be investigated. This might be a very time consuming process and is not supported in the present version of the product. Note that most installations with ABR do not use this option.

Removing unused discrete profiles

When operating an Automatic Data Set Protection (ADSP) environment, sooner or later a number of discrete profiles exist for which no corresponding data set is available. This happens mostly through volume-level operations for which authorization is granted by APF and often in addition by checks in the DASDVOL class. These volume-level operations often do not support discrete profiles. The problem is not necessarily limited to ADSP environment. For example, by default without special RACF exit processing), any user can specify PROTECT=YES in his JCL and/or issue the ADDSD command, at least for data sets starting with his `userid`, and for group data sets if he is connected with CREATE authority.

The unused profiles exist mostly unnoticed in the RACF database. If the volume name is reused and a user tries to allocate a data set for which a profile was left over, the following error message is generated: `RESOURCE ALREADY DEFINED`.

The situation can be highly misleading if a data set exists on the volume with the RACF indicated bit off, which means that DFP does *not* request a search for a discrete profile while at the same time a discrete profile does exist. The RACF LISTDSD command lists the discrete profile for the data set even though the profile is not used for access decision with regard to the data set.

Some security specialists call this a *security exposure*, because users might try to restrict access to the data set by modifying the access list of the discrete profile, while in reality access is *not* restricted due to the fact that DFP only checks the generic profile.

Security zSecure provides a function for reporting and removing the unused discrete profiles. The command to accomplish this is (option **AU.V**):

```
VERIFY DATASET
```

The function is called like this because it verifies that a data set is present for each discrete profile. An equivalent (alias) command, which is easier to remember, is:

```
VERIFY ONVOLUME
```

A CKFREEZE file is required for this function.

If Automatic Backup and Recovery (ABR) is used with the PROFKEEP option, a discrete profile for a migrated non-VSAM data set is assumed to protect it. This assumption is incorrect if the data set does not have the RACF indicated bit on; to verify whether this is the case, however, would necessitate investigating the migration copy, to which end all the migration (DASD and) tapes would have to

be investigated. This might be a very time consuming process and is not supported in the present version of the product. Note that most installations with ABR do not use this option.

Relevant parts of the output from this command are shown in Figure 253. The error messages distinguish three cases: no data set present on volume, volume not mounted, and data set present but not RACF-indicated. In addition, summary messages per volume are printed.

Figure 253. Sample VERIFY ONVOLUME output

Commands can be generated to remove the unused discrete data set profiles by allocating the CKRCMD file.

For unused single volume discrete profiles, commands are generated to remove the profile.

For *multivolume* discrete profiles, commands are generated to remove the volumes from the profile that did not contain the data set. If the data set is not present on *any* of the volumes in the profile, the last command generated is refused by RACF, since the profile is not multivolume anymore. A second VERIFY run generates the command to remove this profile.

Removing unused generic profiles

While an environment with generic profiles contains considerably fewer profiles than an all-discrete environment, discrete profiles do have one big advantage over generics: they are deleted when the data set is deleted. The complete ban on discrete profiles (as some sites have done) can lead to a proliferation of generic profiles that have been created for the purpose of setting a permit on one data set, but that have not been deleted when the data set was deleted.

Security zSecure assists in this problem by providing a function that can automatically generate commands to remove *empty* generic data set profiles, for example, data set profiles that are not used for the protection of any currently existing data set. Two options exist for this function: removing *all* empty generic profiles, or only generic profiles also covered by a less specific profile. The last option is generally preferable in a PROTECTALL environment, since removal of the last generic profile potentially covering a new data set will prevent allocation of that new data set.

For the function to perform properly, a CKFREEZE file is required containing VTOC, VVDS, BCS (catalog), HSM MCDS, DMSFILES, ABR, RMM, TLMS VMF,

and CA1 TMC information. *If the catalog information is not present, VSAM data sets are left out, which can increase the number of profiles found to be empty.*

Do not use this function in an ADSP environment with PROTECTALL active because in that case all data sets are covered by discrete profiles, resulting in all generics being considered empty. However, the generics are required in practice to create new data sets with discrete profiles and have them restored from backups.

Likewise, you should be careful in using the ALLNOTEMPTY variant of this function if you use Automatic Backup and Recovery (ABR) with the PROFKEEP option, since the product does not investigate the migration tapes, and hence *assumes* the RACF indicated bit to be set if a discrete profile exists for the data set. If this turns out to be false, the data set might actually be covered by a generic profile that is considered empty.

If you currently do not have the SETROPTS TAPEDSN option active, the existence of tape data sets does not cause the profiles to be considered non-empty. If this is the case, the program prepares for future activation of the TAPEDSN option by including the following command:

```
SIMULATE SETROPTS TAPEDSN
```

This assures that generic profiles that cover only data sets on tape are not deleted.

The function is called by the following command (option **AU.V**):

```
VERIFY NOTEMPTY
```

or, if you are sure that you want to have the *last* generic profile removed:

```
VERIFY ALLNOTEMPTY
```

To generate commands, allocate the CKRCMD file.

Relevant parts of the output from this command are shown in Figure 254.

Figure 254. Sample VERIFY NOTEMPTY output

Finding and resetting unnecessary RACF indicated bits

If a data set is RACF indicated, DFP requests a search for a discrete profile. If the profile is not present, then generic processing is started. The latter process is known as *always-call*: RACF is always called to to search for a generic profile even if the data set is not RACF indicated or if the data set is indicated but no discrete profile was found. [4] . This processing behavior can create unnecessary I/O overhead for data sets that are RACF indicated but do not have a discrete profile.

4. Security zSecure operations presuppose an *always-call* environment. All systems with DFP or DFSMS have always-call.

The normal situation is that the data set is *not* RACF indicated, avoiding the overhead of trying to find a discrete profile in the database before using a generic profile (generics are retained in-storage once referenced).

The situation is typically created by backup/restore operations without a proper RACF interface for discrete profiles, or by conversions to generic profiles that used DELDSD NOSET to remove the discrete profiles. In addition, a number of 'hard cases' can exist that can only be removed by using alternate IPL parameters, like page data sets, and SMF data sets.

Security zSecure provides a function to report on RACF indicated data sets without discrete profiles. This function generates commands to add discrete profiles for these data sets. To properly reset the indicators, these discrete profiles can be removed later on with the REMOVE REDUNDANT command discussed in "Finding and removing redundant profiles" on page 366.

The function to generate the discrete profiles is available from the Audit Verify option (**AU.V**) on the main menu. You can also access the function by issuing the following command:

```
VERIFY INDICATED
```

A CKFREEZE file is required for this function.

If Automatic Backup and Recovery (ABR) is used with the PROFKEEP option, discrete profiles for migrated non-VSAM data sets might or might not be redundant, depending on the RACF indicated bit which cannot be determined without investigating the migration tapes. These profiles are not included in the report.

Relevant parts of the output from this command are shown in Figure 255:

```
Include CKRALLOC (ISPF variable)
    2 |/* Data from DD070525 */
    3 |alloc type=UNLOAD dsn='SYSAPPL.CNRACF.DD070525.UNLOAD'  complex=DD070525

Figure 255. Sample VERIFY INDICATED output

The messages in the example are generated in their default order (by message type). You can use the BY parameter of VERIFY to change the order.

Commands can be generated to add discrete data set profiles by allocating the CKRCMD file.

Finding user/group/connect inconsistencies

Information about the user/group structure is stored in the RACF database in a redundant way. To be precise, the RACF database stores the information 3 times:

on the USER profile, on the GROUP profile, and on the CONNECT profile (for non-restructured databases) or in a repeat group in the USER profile (for restructured databases).

Some events can destroy the consistency of these 3 information sources on connects. E.g. the system can go down during a RACF command, or the system can be operating with inconsistent *database range tables* across shared systems.

Security zSecure provides a function to verify the consistency of these 3 information sources. This is done by the following command (option **AU.V**):

```
VERIFY CONNECT
```

The following example examines in a healthy database what problems would be recognized if the base segment of user C##BJTI would somehow become unrecognizable (by instructing the program to pretend it is not there with a global EXCLUDE statement in SETUP PREAMBLE).

Relevant parts of the output from this command are shown in Figure 256.

```
Include CKRALLOC (ISPF variable)
    2 |/* Data from DD070525 */

CKR0066 08 Missing group    C##B     on user C##BJTI
```

Figure 256. Sample VERIFY CONNECT output

No commands are generated by Security zSecure to remedy the situation, since the best course of action depends on a number of factors. For instance, it is undesirable to delete a user profile and add it again if many data set profiles have to be preserved. Sometimes, a sequence of REMOVE and CONNECT commands does the job. Sometimes, however, the BLKUPD utility is needed. If IBMUSER is one of the user IDs involved, carefully study the RACF documentation. Each IPL, the IBMUSER user ID is recreated if it is missing, but this does not necessarily apply to its connects.

Converting to generic profiles

Conversion from an Automatic Data Set Protection (ADSP) environment to a PROTECTALL environment with mainly generic profiles generally includes the following sequence of steps:

1. Decide on access requirements. For instance, batch jobs that use unprotected data sets must be identified, as well as the batch `userid`s used.
2. Make a list of all groups that have ALTER access on a generic DATASET profile that has this same group as the High-level qualifier. Example: SYS1.APF.** might have group SYS1 with ALTER access. This is needed to assure that users that had a connect with CREATE authority do not lose the authority to create new group data sets after PROTECTALL has been activated and their ADSP attribute has been reset. To continue the preceding example, make sure that SYS1.** has SYS1 in the access list with ALTER access.

3. Activate PROTECTALL(FAIL).
4. Remove user or connect ADSP attributes synchronously with removing production JCL steps containing explicit PERMIT commands. This synchronization might be necessary if production JCL uses explicit PERMIT commands to tailor the access list of data sets (and hence, profiles) newly made in previous steps (poor man's profile modelling), and in addition aborts the production job sequence if a nonzero return code is issued (which would be the case if ADSP were turned off globally - the PERMIT command would issue return code 12 because no profile would exist). Using just the system-wide SETROPTS NOADSP instead is possible if all these conversions can be scheduled at the same time or if your production JCL does not contain dependencies on correct execution of RACF commands on discrete profiles - see also the background item below.
5. Remove PROTECT=YES statements in JCL, as well as PROTECT keywords on ALLOCATE commands.
6. Remove discrete profiles with the same properties as the generic profile. These profiles are *redundant*.
7. Define generic profiles for groups of similar profiles not covered by the standard generic profile, and remove the discrete profiles that have become redundant by the addition of the generic profile.

zSecure provides assistance in this process by means of the SELECT ADSP (step 4), REMOVE REDUNDANT (step 5), and REPORT NONREDUNDANT (step 6) commands. These are discussed in “Finding profiles with specific attributes” on page 1684,“RA.3.2 Non redundant - Data set profiles different from less specific profiles” on page 201, and “Finding and removing redundant profiles,” respectively.

zSecure Audit for ACF2 provides assistance in this process by means of the NEWLIST TYPE=SMF. This can be used to trace access to unprotected data sets, including the access level used. See the zSecure Audit for ACF2 CARLa script CKALFNPR.

Background - removing ADSP

With respect to step 4, removing ADSP, you must be aware that this is difficult to perform on a group-by-group basis if you have activated list-of-group processing. The ADSP attribute used by RACF is *not* the ADSP attribute on the CONNECT for which a data set profile is being CREATEd, but instead the ADSP attribute of the *current connect group*.

Finding and removing redundant profiles

Security zSecure provides a function specifically designed to aid in the conversion from ADSP to generic profiles. This is done by automatically generating commands to delete discrete profiles that give *similar* ("equivalent") access to that resulting from the combination of the most specific matching generic data set profile and the most specific matching global table entry (if present).

If you use Automatic Backup and Recovery (ABR) with the PROFKEEP option, you should be aware that on restore of a non-VSAM data set that must be recreated, ABR will request a default discrete profile to be created via ADSP if its RACF indicated bit was set on migration. In addition, this RACF indicated bit is only available on the migration tapes, which currently are not checked; instead it is assumed that an existing discrete will apply. If a data set is already allocated, ABR will fail the restore unless the RACF indicated bits match. Therefore, if you are converting from ADSP to generic profiles, we recommend that you consider the implications regarding ABR *first*, and review the commands generated to remove profiles bearing this in mind.

For a profile to be considered *redundant*, three profile properties are checked:

1. Access requirements (access list, conditional access list, and universal access).
2. Audit requirements (failure audit level, success audit level).
3. Erase-on-scratch requirement.

The last two items are simply compared to those of the most specific matching generic profile, called the *candidate* profile. They must be equal before the profile is considered redundant. However, the *erase-on-scratch* requirement is not checked if the system wide option ERASE(ALL) or NOERASE is active.

The access requirement comparison is more complicated. Simplest is the *universal access* (UACC) comparison. For a profile to be considered redundant, its UACC must either be equal to that of the candidate profile, or less than ALTER and at the same time less than or equal to the most specific matching entry of the global access table, for example a member of the DATASET profile in class GLOBAL).

The *access list* and *conditional access list* comparison considers the account group membership for user IDs in the list. That is, a user ID in the conditional list of a redundant profile might be missing from the conditional access list of the candidate profile only, if one of the connect groups is present with the same access (and the same program name), and no connect groups are present with a higher access (and the same program name).

TheYou can access the command generation function fom option **RA.3.3** or by issuing the following command:

```
REMOVE REDUNDANT
```

Optionally, the number of profiles processed can be limited to a group of data sets by means of SELECT commands, `SELECT QUAL=id` for example.

For information about the method for showing non-redundant profiles and the reason they are non-redundant, see “RA.3.2 Non redundant - Data set profiles different from less specific profiles” on page 201.

Note: The redundancy check does not take all fields into account. For example, the RESOWNER and NOTIFY fields, and security categories, levels, and labels are not checked.

Finding inconsistencies in started task definitions

Started tasks are initiated by the `START` operator command, specified with an optional `SUB=` parameter to indicate a target subsystem. The default subsystem is the primary subsystem, usually JES2 or JES3. Security zSecure supports both JES2 and JES3 as the primary subsystem. It also supports the MSTR subsystem that is present in every MVS system.

When a started task is initiated, RACF first looks for a profile in the STARTED class with the format *procedure.jobname* to determine the user or group identity to assign to the task. If there is no such profile, or the profile does not contain an STDATA segment or STUSER specification, RACF falls back on the Started Procedure Table (ICHRIN03) to look for a match. You can use the STARTED and STCTABLE reports to review the contents of the STARTED class and the Started Procedure Table. See "STCTABLE - Started Procedure Table and Started Class" on page 288. To see the identities assigned to the started tasks, see "STCPROT - Started Task protection report" on page 344.

You can verify the consistency of the three information sources (ICHRIN03, RACF database, and procedure libraries) by issuing the **VERIFY STC** command.

The results of this function are only reliable when you supply a CKFREEZE file that was produced by running zSecure Collect from an authorized library. If you do not follow this requirement, STARTED profiles and ICHRIN03 entries can be incorrectly flagged as unused.

Be cautious about running the commands generated by the RDELETE command. If zSecure Collect is run with APF authorization, the program searches across memory functions to find the data sets allocated to STCPROC, or PROC00 if STCPROC is not available. Subsequently, it reads the PDS directory of each of these procedure libraries. It is insufficient to tell zSecure Collect to dump the directories of the PDS data sets in an unauthorized run because they are not recognized as procedure libraries.

For the STARTED class, the program checks for the following problems or inconsistencies:

1. Inactive classes that contain profiles that were never used.
2. Classes with profiles that do not cover any started task, as determined from the supplied CKFREEZE files.
3. Started tasks not covered by any profile that cause RACF to fall back to ICHRIN03 which is not advisable.
4. Profiles that do not have an STDATA segment.

   ICHRIN03 is used instead.
5. Profiles that do not have an STUSER specification in the STDATA segment.

   ICHRIN03 is used instead.
6. Profiles that have an STUSER specification that is not a valid RACF user ID.

   The JES undefined user is used instead.
7. Profiles that have an STGROUP specification that is not a valid RACF group ID.

   The JES undefined user is used instead.
8. Profiles that have valid user and group specifications that are not connected.

   The JES undefined user is used instead.
9. Profiles that specify a revoked user.

   This causes the started task to run with reduced authority, which might cause problems.

The verification function checks for these problems and issues commands to fix them if possible. The checks are performed based on the following processing rules:

- If the STARTED class is inactive, checks 2 through 9 are not performed.
- Checks 4 through 9 are only performed for profiles covering started tasks.

- If you are not interested in checks 6 on page 368 though 8 on page 368, add a SUPPRESS ID=++++++++ statement to the input commands. The checks are still done, but no commands are issued to fix any problems found. Also, if these checks fail, a further failure on check 9 on page 368 is not reported.

  Note: If you have changed the JES undefined user from ++++++++ to something else, specify the actual value on the suppress statement. This value is reported in the SETROPTS report in "SETROPTS - RACF settings report" on page 266 under the heading "Job Entry Subsystem options" as "Default uid local UNDEFINEDU". This value is also available in the UNDEFINEDUSER field of a SYSTEM NEWLIST .

For both the STUSER and STGROUP, the specification =MEMBER can be used instead of an explicit RACF user ID or group ID. This means that the member name of the started task being initiated is substituted for STUSER and STGROUP and matches a valid RACF user ID or group ID. (Obviously, this can never hold for both STUSER and STGROUP at the same time). As a result, some problems can be detected by simply looking at the STARTED profile (either does not contain =MEMBER, or has a discrete first qualifier which unambiguously identifies the substitution, or contains =MEMBER twice). Other problems require the evaluation of the member name and can only be detected on the started task level. For errors on the profile level, the program issues a single message for it. For some errors, the program might generate a command to try to fix the problem. For errors on the member level, the program issues a message on the member level, which can amount to several messages for a single profile. The program does not attempt to identify a fix for the error.

If more than one problem is detected, and the problems are of the same importance, they are both reported. However, if both a profile level problem and a member level problem are detected, only the profile level problem is reported. Therefore, after correcting the profile problems identified in the report, run the report again to identify any member level problems that might have been hidden in the initial report.

The following fixes can be generated to prevent profile errors:

- RDELETE is generated for an unused profile.
- For a profile without an STDATA segment, an STDATA segment with STUSER specification is created.
- Invalid STUSER or STGROUP specifications are deleted or replaced by =MEMBER if the specifications are clearly invalid.
- If =MEMBER is specified twice with a generic first qualifier, the STGROUP specification is deleted as this is the only solution that produces a usable profile.

The program does not generate any commands to address the following issues:

- Missing STUSER specification.
- Missing connection.
- Revoked user ID.
- Member level problems

If the STUSER specification is missing, the program purposely falls back to the Started Procedure Table ICHR1N03 which is the known solution for this problem. For the other problems, commands are not generated because the program cannot automatically determine what action or change is required to fix the problem.

For the Started Procedure Table ICHRIN03, the program checks for the following problems or inconsistencies:

1. Entries that do not cover any started task.

   This condition might be acceptable as a fallback when the STARTED class is inactive.
2. Started tasks that are not covered by any entry.

   These tasks are run with the default RACF user '*' , so this condition might not require a fix.
3. Generic entries that are not the last entry.

   These entries are not used.
4. Generic entries with a blank group name.

   If these entries exist, any user that can define started tasks can masquerade as any user.
5. Generic entries with the privileged or trusted attribute
6. Entries with a user specification that is not a valid RACF user ID.

   For these entries, the default RACF user '*' is used.
7. Entries with a group specification that is not a valid RACF group ID.

   For these entries, the default RACF user '*' is used.
8. Entries that have valid user and group specifications that are not connected.

   For these entries, the default RACF user '*' is used.
9. Entries that specify a revoked user.

   If the user has been revoked, the specified procedure cannot be started.
10. Entries with a valid user and group that have a revoked connect.

    If the connect has been revoked, the specified procedure cannot be started.

ICHRIN03 entries are even checked when they do not cover any started task because there are no matching tasks or because the tasks that match use a STARTED class profile instead. You can specify the SUPPRESS FALLBACK option, in which case only those entries that are currently in use are thoroughly checked for referential integrity and other problems. If this option is enabled, unused entries are still flagged. You might not want to use the suppress option if you want to check Fallback entries that are important because they are used to IPL the system when the STARTED class is inactive.

Figure 257 on page 371 shows relevant parts of the data from the VERIFY STC function. A CKFREEZE file is required for this function.

```
Include CKRALLOC (ISPF variable)
    2 |/* Data from DD070525 */
    3 |alloc type=UNLOAD dsn='SYSAPPL.CNRACF.DD070525.UNLOAD'  complex=DD070525
    4 |

```

Figure 257. Sample VERIFY STC output

If the (possibly many) messages CKR0326 are not required, they can be suppressed by SUPPRESS MSG=326. The same holds for messages 576 and 577; recall in the case of CKR0577, however, that suppressing a message will not suppress the associated command (RDELETE in this case).

The generated commands look like the commands in the following figure.

```

Auditing CKGRACF

You can audit the use of CKGRACF using the following CKGRACF features.

- The SHOW CKRSITE command displays the installation-defined settings stored in the CKRSITE module. For details, see "The CKRSITE module" on page 372.
- After a CKGRACF command completes, a RACF SMF record (SMF 80, EVENT=GENERAL) is written which records information about the command and its effects. For details, see "RACF processing records" on page 373.

- If CKGRACF profiles are being audited, each RACF logging record for these profiles (SMF 80, EVENT=ACCESS) contains a description of the command being executed and the CKGRACF application name. For details, see “RACF processing records” on page 373.
- All CKGRACF settings in user profiles contain a stamp with the command-issuing user and the date and time the command was executed. This stamp is displayed with the LIST USER command and in the USR field in Security zSecure. For details, see “CKGRACF settings in the user profile” on page 376.
- Completed queued commands and wiped scheduled actions are not deleted immediately, but remain in the user profile until an installation-defined auditing period has passed. For details, see “CKGRACF settings in the user profile” on page 376.

Note that Security zSecure also provides support to audit CKGRACF. For example, the REPORT SCOPE command reports the users and groups within the CKGRACF-defined scope. For details, see “REPORT” on page 875

The CKRSITE module

The optional CKRSITE module contains the installation-defined settings for CKGRACF. These settings can be displayed using the SHOW CKRSITE command, which results in output like in Figure 258.

```
CKGRACF SHOW CKRSITE
CKG100I 00 Contents of CKRSITE module:
           Class:              XFACILIT
           Authority:          SINGLE
           Command expiration: 7
           Audit expiration:   30
```

Figure 258. Sample output of the SHOW CKRSITE command

The meaning of the listed settings is:

- The class checked for CKGRACF profiles is XFACILIT. Thus, when the manual refers to 'command resource name CKG.CMD.REFRESH', the XFACILIT class is checked for a profile matching that resource name.
- The default multiple-authority setting is SINGLE. This means that any user without a multiple-authority requirement of its own, is subject to single authority. Other options are DUAL and TRIPLE.
- The command expiration time is 7 days. This means that a queued command must be acted upon within 7 days of the last action. After 7 days, the queued command expires and can no longer be executed.
- The Audit expiration time is 30 days. This means that completed or expired commands, and ineffective or wiped scheduled actions are deleted after 30 days. Until that time, the completed commands and wiped scheduled actions can be displayed using the LIST USER command.

You should verify that these options are the same in the CKRCARLA program. The Security zSecure command SHOW CKRSITE can be used to display those settings.

RACF processing records

Background

At the end of each CKGRACF command, a RACF processing record (SMF 80) is written with EVENT=GENERAL. The EVENT=GENERAL record contains the following fields of interest:

- The DESCRIPTOR field (SMF80DES) indicates whether the command succeeded or failed. (The RACF report writer RACFRW describes this as VIOLATIONS and SUCCESSES.)
- The LOGSTR field contains the CKGRACF command and always starts with the word *CKGRACF*. The log string never contains sensitive data like passwords. You can select records with a log string of this format with the option LOGSTR=:CKGRACF. The RACF Report Writer (RACFRW) describes this field as LOGSTR.

  The log string in a RACF SMF record can have 255 characters at most. Some parts of CKGRACF commands with more than 255 characters are not logged because they exceed this length. The length is typically exceeded on commands that have very long REASON strings. Devising a shorterREASON string can prevent commands from being omitted from the logs.
- The USER and GROUP fields–*SMF80USR* and *SMF80GRP*, for example, contain the name of user who issued the command along with the current connect group for that user.
- The CLASS and PROFILE fields contain the class and profile name of the target profile. For example, a CKGRACF USER command has CLASS set to USER and PROFILE set to the target userid. This feature is only available with zSecure Audit for ACF2, not with the RACFRW.

If the CKGRACF profiles are being audited, RACF processing records (SMF 80) are written with EVENT=ACCESS. When access violations are selected, all failed access checks are found; when access successes are selected, all successful access checks are found. However, in those cases where CKGRACF permits access because one profile out of several granted access based on the USR scope check for example, a success is logged on the first profile granting access or failure is logged on all profiles that denied access. Consequently, if the third step in the USR scope check grants access, failures are not logged for the first two steps in the scope check.

A profile can be audited using the RALTER GLOBALAUDIT command. For example, to audit access failures to the profile CKG.CMD.AUTHORITY, and successful access to the profile CKG.CMD.RDELETE, use the following commands:

```
RALTER XFACILIT CKG.CMD.AUTHORITY GLOBALAUDIT(FAILURES(READ))
RALTER XFACILIT CKG.CMD.RDELETE GLOBALAUDIT(SUCCESS(READ))
```

See the 'Security Server RACF Auditor's Guide' and the 'Security Server RACF Command Language Reference' for more details.

The EVENT=ACCESS record contains the following fields of interest:

- The DESCRIPTOR field (SMF80DES) indicates whether the command succeeded or failed. (The RACFRW describes this as VIOLATIONS and SUCCESSES.)
- The LOGSTR field usually contains the command string which always starts with the word CKGRACF. (The log string never contains sensitive data such as passwords.) Selecting the records with a log string of this format can be done using LOGSTR=:CKGRACF. (The RACFRW describes this field as LOGSTR.) Incidentally, the log string can be missing from a RACF record written by

CKGRACF with EVENT=ACCESS. RACF records written by CKGRACF with EVENT=ACCESS can be selected regardless of a missing LOGSTR using LOGSTR=:CKGRACF,OR,APPL=CKGRACF.

- The USER and GROUP fields (SMF80USR and SMF80GRP) contain the name of the command-issuing user and his or her current connect group.
- The EVENTQUAL field (SMF80EVQ) contains the numerical event qualifier, which describes the kind of access event. (The RACFRW describes this field as EVQUAL.)
- The RESOURCE field contains the resource name checked. (The RACFRW describes this field as NAME or RESOURCE.)
- The PROFILE field contains the profile checked. In the case of a discrete profile, this is identical to RESOURCE; in the case of a generic profile, this is the real profile checked. (This field is not listed by the RACFRW.)
- The ACCESS and INTENT fields contain the intended and permitted access.

Auditing RACF processing records

To audit the use of CKGRACF profiles and commands, the standard query "CKGRACF" is available under menu option **EV.2**. Select that query, and complete the selection criteria in the next panel, then press enter to start the query. A sample display is shown in the following figure.

```
SMF record RACF processing and audit records                  Line 145 of 1300

  Profile owner id
  Installation data

  Subject identification
_ User:  C##QAP1      Group: C##QA        Terminal:            Appl:
  Name:  GRPSPEC RACFWIN USER             Security label:
  Token: User:C##QAP1; Group:C##QA; Session:OMVSSRV
****************************** BOTTOM OF DATA ********************************
```

Violations are recorded in the log record as shown in the following example:

```
User C##QAP1 was not permitted to set the password for user ADM1.
```

In the log record, the requested password is replaced by asterisks. If the class configured in the CKRSITE module has the proper logging for RACF, an access violation is also written showing the profile that prevented access.

In this particular case, the preceding record shows a failed CKGRACF profile check as shown in Figure 259 on page 376: User *ADM1* is not in the ID-scope of *C##QAP1* and the id-hierarchical (SCP.G/U) scope check also failed, so the CKGRACF command is refused. See "Scope profiles" on page 1563 for a detailed explanation.

Figure 259. SMF record RACF processing and audit records panel

CKGRACF settings in the user profile

All CKGRACF settings in the user profile contain a stamp with the command-issuing user and the date and time the command was executed. The settings and the stamp can be displayed using the CKGRACF LIST command. The LIST command displays the following types of information:

- Multiple-authority settings.
- The availability of a default password.
- All scheduled revoke/resume events.
- All queued commands.

All completed queued commands and past scheduled revoke/resume settings that lie within the installation-defined auditing period are kept in the user profile and are also displayed. Figure 260 on page 377 shows sample output of the LIST USER command; note that withdrawn queued commands and deleted scheduled actions are also listed.

```
CKGRACF LIST USER C##CX02

------------ Status of USER C##CX02 on 10Nov1999 17:17 at DINO -------------

```

Figure 261. Sample Security zSecure detail display of the USR field

As described in "RA.2 QUEUED - Queued commands" on page 185, line commands can be used to approve, hold, or deny queued commands, and to copy or add new queued commands, schedules, and installation-defined USR entries.

Predefined CARLa scripts

In this section, the ISPF and batch sample reports available in the SCKRCARL library are discussed. The convention used to name CARLa scripts members is explained in "Naming convention" on page 706.

Interactive reports

The following interactive (ISPF) RACF reports are available.

Table 187. Interactive RACF reports

Report	Meaning
CKAD@CO	Audit concerns for RACF control for creating the audit concern overview.
CKAD@RO	Audit concerns for resource protection (used to build audit concern overview)
CKADRFIL	Show sensitive UNIX files. Automatically included by CKRDAC1.
CKADRFW	Show globally writable UNIX files. Automatically included by CKRDRGBW.

Table 187. Interactive RACF reports (continued)

Report	Meaning
CKADRPAU	RACF profile audit concerns.
CKADRTRU	Show sensitive resources with trustees
CKADRUGD	Show UNIX UIDs and GIDs, used somewhere in a UNIX file system but not defined to RACF.
CKADSD80	Audit concerns for RACF SETROPTS settings (80 characters wide). Automatically included by CKRDSD80.
CKADSR80	Audit concerns for RACF settings and options. Automatically included by CKRDSR80.
CKADUTRU	Show trusted users.
CKRDAC1	Protection of APF modules (REPORT AC1). Automatically includes CKADRFIL.
CKRDAUTH	Authorized user (Special, Operations, Auditor) report. This also shows the class authorizations, and users with uid 0.
CKRDCLAS	Class Descriptor Table, SETROPTS settings, and RACF profiles report.
CKRDDCLS	RACF class info from database ICB
CKRDENT#	Entity and segment summary.
CKRDGAU	Group-authorized user report.
CKRDGLOB	Global Access Table overview.
CKRDLGAD	Overview of user by last logon date, detailed report.
CKRDLGAG	Overview of last logon ages, summary only.
CKRDLGER	Overview of users with logon failures (detailed).
CKRDLGE0	Over of users with logon failures (concise).
CKRDLGNU	Overview of users that have never been used.
CKRDLGRV	Userids with pending revoke due to inactivity.
CKRDOMVS	Show users with duplicate UIDs and groups with duplicate GIDs
CKRDPADS	Program Access to Data Sets (REPORT PADS).
CKRDPWAD	Overview of password ages, detailed report.
CKRDPWAG	Overview of password ages, summary only.
CKRDPWIN	Overview of users with exceptional password interval.
CKRDPWNU	Overview of users with initial passwords.
CKRDPWXP	User IDs with expired passwords.
CKRDRGBW	Show global write access. Automatically includes CKADRFW.
CKRDRROV	Summary table of general resource profiles.
CKRDSAUT	RACF Authorized Caller Table.
CKRDSD80	RACF SETROPTS settings in database. Automatically includes CKADSD80.
CKRDSDSN	RACF Data Set Name Table.
CKRDSENP	Profiles covering sensitive data (REPORT SENSITIVE)
CKRDSPT	RACF Started Procedures Table and STARTED class.
CKRDSRFR	SAF Router Table.

Table 187. Interactive RACF reports (continued)

Report	Meaning
CKRDSRNG	RACF Data Set Range Table.
CKRDSR80	RACF settings and options. Automatically includes CKADSR80.
CKRDSTC	Protection of started tasks (REPORT STC).
CKRDTEMP	RACF template display (with detail selection)
CKRDTEM0	RACF template display (no detail selection)
CKRD2DIF	Compare profile existence in 2 RACF databases (edit data set names first)

Batch reports

The following batch RACF reports are available (these start with CK%L or CKRR). The CKRR* members are the original (backward compatibility) layouts for a number of REPORT command parameters.

Table 188. CARLa scripts - Batch reports

Report	Meaning
CKAL$ALL	Collection of all system and many RACF-specific reports
CKAL$CD	Collection of reports on RACF control
CKAL$RD	Collection of reports on resources for RACF
CKAL$UD	Collection of reports on RACF users
CKAL@ALL	Overview of audit concerns from all system and many RACF-specific reports
CKAL@CO	Audit concerns for RACF control (used to build audit concern overview)
CKAL@RO	Audit concerns for resource protection with RACF (used to build audit concern overview)
CKALRFIL	Show sensitive UNIX files. Automatically included by CKRLAC1.
CKALRFW	Show globally writable UNIX files. Automatically included by CKRLRGBW.
CKALRPAU	RACF profile audit concerns.
CKALRTRU	Show sensitive resources with trustees.
CKALRTR0	Show sensitive resources (concise).
CKALRUGD	Show UNIX UIDs and GIDs, used somewhere in a UNIX file system but not defined to RACF.
CKALSD13	Audit concerns for RACF SETROPTS settings (132 characters wide). Automatically included by CKRLSD13.
CKALSD80	Audit concerns for RACF SETROPTS settings (80 characters wide). Automatically included by CKRLSD80.
CKALSR13	Audit concerns for RACF settings and options (132 characters wide). Automatically included by CKRLSR13.
CKALSR80	Audit concerns for RACF settings and options (80 characters wide). Automatically included by CKRLSR80.
CKALUTRU	Show trusted users (detailed).
CKALUTR0	Show trusted users (concise).

Table 188. CARLa scripts - Batch reports (continued)

Report	Meaning
CKRL$ALL	Collection of RACF reports.
CKRLAC1	Protection of APF modules (REPORT AC1). Automatically includes CKALRFIL.
CKRLAPPL	Overview of APPL application profiles.
CKRLAUD	Show non-default auditing parameters (audited users, success audit, non-default failure audit).
CKRLAUTH	Authorized user (Special, Operations, Auditor) report, including class authorizations, and uid 0.
CKRLCICS	Resolved access list of all CICS-related profiles.
CKRLCICT	Resolved CICS transaction authorization report (combines members of grouping profiles with member profiles)
CKRLCLAS	Overview of CDT and SETROPTS settings.
CKRLCLS#	Class info for classes with one or more profiles.
CKRLDB2	Overview of DB2-related profiles, and users with CICS, DDF, or IMS access to DB2®.
CKRLDCLS	RACF class info from database ICB
CKRLENT#	Entity and segment summary.
CKRLGAU	Group-authorized user report.
CKRLGLOB	Global Access Table overview.
CKRLGRPI	Two-pass query to show group tree with added user information, to aid in designing administration authorities.
CKRLGRPT	Group-tree overview.
CKRLIMS	Overview of IMS-related profiles.
CKRLINAC	Overview of inactive users.
CKRLJES2	Overview of JES2-related profiles.
CKRLLGAD	Overview of last logon date, detailed report.
CKRLLGAG	Overview of last logon date, summary only.
CKRLLGER	Overview of users with logon failures.
CKRLLGNU	Overview of users that have never been used.
CKRLLGRV	Show user IDs with pending revoke due to inactivity.
CKRLMTX1	Two-pass query to show a data set access matrix for selected users (customization is necessary).
CKRLMTX2	Two-pass query to show a connection matrix for selected `userids` and groups (customization is necessary).
CKRLMTX3	Query to obtain a matrix of userids with access to selected data set profiles (imbed member after RACFSEL selection NEWLIST; see member for an example).
CKRLOMVS	Show users with duplicate UIDs and groups with duplicate GIDs.
CKRLPADS	Program Access to Data Sets (REPORT PADS).
CKRLPROG	Program profile and PADS overview.
CKRLPWAD	Overview of password age, detailed report.
CKRLPWAG	Overview of password age, summary only.

Table 188. CARLa scripts - Batch reports (continued)

Report	Meaning
CKRLPWIN	Overview of users with exceptional password interval.
CKRLPWNU	Overview of users with initial passwords.
CKRLPWXP	Show `userids` with expired passwords.
CKRLREV	Overview of revoked users and (non-RDS only) revoked connects.
CKRLRGBW	Show global write access. Automatically includes CKALRFW.
CKRLSAUT	RACF Authorized Caller Table.
CKRLSCPS	Two-pass query to show scope reports for more than one user.
CKRLSD13	RACF SETROPTS settings in database (132 column display). Automatically includes CKALSD13.
CKRLSD80	RACF SETROPTS settings in database (80 column display). Automatically includes CKALSD80.
CKRLSDSF	Overview of SDSF-related profiles.
CKRLSDSN	RACF Data Set Name Table.
CKRLSENP	Profiles covering sensitive data (REPORT SENSITIVE).
CKRLSPT	Started Procedure Table and STARTED profiles.
CKRLSRFR	SAF Router Table.
CKRLSRNG	RACF Data Set Range Table.
CKRLSR13	RACF settings and options (132 column display). Automatically includes CKALSR13.
CKRLSR80	RACF settings and options (80 column display). Automatically includes CKALSR80.
CKRLSTC	Protection of started tasks (REPORT STC).
CKRLTAPE	Overview of TAPEVOL profiles.
CKRLTEMP	Template display (used by SHOW TEMPLATE).
CKRLUNAM	Overview of user names and installation data.
CKRLVHL	Userids and groups for which no high level (catchall) profile was found.
CKRLVSTD	Verify that the owner of a data set profile is the high-level qualifier.
CKRLVSTG	Verify that the owner of a group is the superior group.
CKRLVSTU	Verify that the owner of a user is the default group.
CKRRAC1	REPORT AC1 default layout (used if no NEWLIST TYPE=REPORT_AC1 was specified)
CKRRPADS	REPORT PADS default layout (used if no NEWLIST TYPE=REPORT_PADS was specified)
CKRRSENS	REPORT SENSITIVE default layout (used if no NEWLIST TYPE=REPORT_SENSITIVE was specified)
CKRRSTC	REPORT STC default layout (used if no NEWLIST TYPE=REPORT_STC was specified)
CKRVTCB	List and check protection of Trusted Computing Base

Table 188. CARLa scripts - Batch reports (continued)

Report	Meaning
CKRVWORM	Report globally writable resources. Globally writable data sets can be used to install trojan horses.
C2RL$UNL	Create RACF and ACF2 unload and report statistics

We advise you to run the overall report, CKRL$ALL, at least once. You are then able to decide which reports are useful at your installation, and which sample reports must be edited.

Chapter 4. Resource reports

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The **RE Resource reports** option available on the zSecure Audit Main menu shown in Figure 262 provides access to display and reporting options for RACF resources. You can access additional display and reporting options from the Audit Status (**AU.S**) option available on the Audit menu as described in Chapter 3, "RACF Audit Guide," on page 255.

Note: The Main menu is available from the interactive ISPF application available under both MVS/TSO and VM/CMS. For instructions on starting this application, see "Starting the interactive component" on page 9. For information about panel structure and operation, see "Panel structure" on page 10. For information about any of the fields on any of the zSecure panels, use the field-sensitive help function.

U Unix filesystem reports	"UNIX filesystem reports (RE.U)" on page 390
C CICS region and resource reports	"CICS resource reports" on page 402
M IMS control region and resource reports	"IMS resource reports" on page 413

Table 189. Documentation reference for zSecure Menu options (continued)

Menu Option	Documentation reference
D DB2 region report	"DB2 resource reports" on page 422

IP Stack reports

The RE.I option can be used to select and display TCP/IP stack configuration data. This data is obtained from a CKFREEZE data set created by running zSecure Collect APF-authorized with the `TCPIP=YES` parameter.

When you select RE.I from the main menu, the panel shown in Figure 263 is displayed.

```
 Menu         Options       Info    Commands     Setup
--------------------------------------------------------------------------------
                        zSecure Suite - Resource - IP stack Selection
Command ===> ____________________________________________________   _ start panel

Show TCP/IP stack configuration data that fit all of the following criteria:
Stack name . . . . . ________ (name or filter)
System . . . . . ________ (system or filter)
Sysplex  . . . . . ________ (sysplex or filter)

Output/run options
_  Ports                  _  Rules                  _  VIPA
_  Interfaces             _  Routes                 _  Netaccess
_  AUTOLOG                _  Resolver
_  Output in print format  _  Customize title       _  Send as e-mail
  _  Run in background
```

Figure 263. IP stack Selection panel

From the IP stack Selection panel, you can limit the TCP/IP stack configuration data by entering selection criteria into one or more fields. When you specify selection criteria, only records that match all criteria are included in the output. Filters can be used in some of the selection fields. For a description of the selection fields and to determine whether a field supports filters, use the field-sensitive help function (F1).

You can also specify Output and run options on the Selection panel. The run options (Ports, Rules, VIPA, Interfaces, Routes, Netaccess, and AUTOLOG) allow you to specify additional selection criteria for specific types of IP configuration data. The output run options allow you to specify report and print options. When you select any of these options, the corresponding panels are displayed when you press Enter on the IP stack Selection panel.

If you do not select any Output or run options, the data is processed as soon as you press Enter on the IP Stack Selection panel. An overview panel is immediately displayed with a summary of the IP configuration records that match the selection criteria that you specified.

See the following topics for information about specifying configuration data, selection criteria, and report output options.

"IP stack configuration data: Viewing summary and detail information" on page 385

"IP stack port configuration data - Specifying selection criteria" on page 385

"IP stack rules configuration data - Specifying selection criteria" on page 386

IP stack configuration data: Viewing summary and detail information

After processing the CKFREEZE file, the TCP/IP stack configuration report selection panel is displayed. This panel is displayed immediately from the IP stack Selection panel if you have not selected any of the output or run options. If you have selected output or run options, this panel is displayed after you have entered the required data for the selected options. In Figure 264 the summary data for all IP stack configuration data is listed.

```
         zSecure Suite Display Selection 1 s elapsed, 0.6 s CPU
Command ===> ____________________________________________ Scroll===> PAGE

  Name     Summary Records Title
_ IPSTACK        1       1 Communications Server IP stack display
_ IPPORT         1      33 Communications Server IP ports display

****************************** Bottom of Data ********************************
```

Figure 264. TCP/IP stack configuration report selection

In this example, the overview panel includes information for all of the IP configuration record types based on the selection criteria specified on the IP Stack Selection panel. Only records that match the specified the selection criteria are included.

To filter the summary results by configuration type, you can select a specific IP configuration record type on the Display Selection panel, IPAUTOLOG for example. When the report based on this selection is generated, the overview panel only shows a summary entry for the IPAUTOLOG. To see an overview of the records reported for each configuration type, select the summary line for that type.

From each overview panel, you can navigate to one or more detail panels by selecting a record entry.

For more information about the IP stack configuration reports, see "STATUS AUDIT - MVS tables" on page 440.

IP stack port configuration data - Specifying selection criteria

When you select the **Ports** option on the Resource - IP stack Selection panel (Figure 263 on page 384) opens the panel shown in Figure 265 on page 386 where

you can specify the port attributes you are interested in.

```
 Menu         Options       Info    Commands     Setup
-------------------------------------------------------------------------------
                        zSecure Suite - IP stack - selection
Command ===> ____________________________________________________________

Show ports that fit all of the following criteria:
Port number . . . . . ___________  (port number or range (e.g. 1000:2000))
Jobname . . . . . ________     (jobname or filter)
Bind IP address . . . . ________________________________________
SAF resource name . . . ________     (resource name or filter)
Protocol  . . . . . _  1. TCP      2. UDP      3. Both
```

Figure 265. IP stack - selection - ports

For a description of the selection fields and to determine whether a field supports filters, use the field-sensitive help function (F1). See "IPPORT - Communications Server IP ports display report" on page 490 for more information about the IP_PORT report.

IP stack rules configuration data - Specifying selection criteria

When you select the **Rules** option on the Resource - IP stack Selection panel (Figure 263 on page 384), the Figure 266 is displayed. On this panel, you can specify selection criteria for reporting on IP_RULE configuration data. When you run the report, the results include only the records that match the selection criteria specified on the IP stack Selection panel and on this panel.

```
 Menu         Options       Info    Commands     Setup
-------------------------------------------------------------------------------
                        zSecure Suite - IP stack - selection
Command ===> ____________________________________________________________

Show rules that fit all of the following criteria:
Source IP address . . . ________________________________________
Source IP port  . . . . _____  (number or filter)
Destination IP address  ________________________________________
Destination IP port . . _____  (number or filter)
Protocol  . . . . . _  ICMP   _  TCP    _  UDP    _  ICMPV6 _  OSPF
Routing type  . . . . . _  1. Local    2. Routed   3. Either
```

Figure 266. IP stack - selection - rules

For a description of the selection fields and to determine whether a field supports filters, use the field-sensitive help function (F1). See "IPRULE - Communications Server IP rules display report" on page 492 for more information about the IP_RULE report.

IP stack VIPA configuration data - Specifying selection criteria

When you select the **VIPA** (Virtual IP address) option on the Resource - IP stack Selection panel (Figure 263 on page 384), the Figure 267 on page 387 is displayed. On this panel, you can specify selection criteria for reporting on IP_VIPA configuration data. When you run the report, the VIPA results include only the records that match the selection criteria specified on the IP stack Selection panel and on this panel.

```
 Menu         Options       Info    Commands     Setup
-------------------------------------------------------------------------------
                        zSecure Suite - IP stack - selection
Command ===> ____________________________________________________________

Show VIPA addresses that fit all of the following criteria:
Virtual IP address  . . ____________________________________________
IPV6 interface name . . _______________  (name or filter)
VIPA type   . . . . . . _  1. Backup  2. Define  3. Range   4. All
```

Figure 267. IP stack - selection - VIPA

For a description of the selection fields and to determine whether a field supports filters, use the field-sensitive help function (F1). See "IPVIPA - Communications Server IP VIPA report" on page 492 for more information about the IP_VIPA report.

IP stack interface configuration data - Specifying selection criteria

When you select the **Interfaces** option on the Resource - IP stack Selection panel (Figure 263 on page 384), the panel shown in Figure 268 is displayed. On this panel, you can specify selection criteria for reporting on IP stack interfaces configuration data. When you run the report, the results include only the records that match the selection criteria specified on the IP stack Selection panel and on this panel.

```
 Menu         Options       Info    Commands     Setup
-------------------------------------------------------------------------------
                        zSecure Suite - IP stack - selection
Command ===> ____________________________________________________________

Show interfaces that fit all of the following criteria:
Interface name  . . . . _______________  (name or filter)
IP address  . . . . . . ____________________________________________
Virtual LAN id  . . . . _______________  (id or filter)
```

Figure 268. IP stack - selection - interfaces

For a description of the selection fields and to determine whether a field supports filters, use the field-sensitive help function (F1). See "IPINTFD - Communications Server IP interfaces report" on page 493 for more information about the IP_INTERFACE report.

IP stack route configuration data - Specifying selection criteria

When you select the **Route** option on the Resource - IP stack Selection panel (Figure 263 on page 384), the Figure 269 on page 388 is displayed. On this panel, you can specify selection criteria for reporting on IP Route configuration data. When you run the report, the results include only the records that match the selection criteria specified on the IP stack Selection panel and on this panel.

```
 Menu         Options       Info    Commands     Setup
------------------------------------------------------------------------------
                        zSecure Suite - IP stack - selection
Command ===> ____________________________________________________________

Show routes that fit all of the following criteria:
Source IP address . . . ____________________________________________
Destination IP address  ____________________________________________
Interface name  . . . . ________________  (name or filter)
```

Figure 269. . IP stack - selection - routes

For a description of the selection fields and to determine whether a field supports filters, use the field-sensitive help function (F1). See "IPROUTE - Communications Server IP routes report" on page 494 for more information about the IP_ROUTE report.

IP stack network access configuration data - Specifying selection criteria

When you select the **Netaccess** option on the Resource - IP stack Selection panel (Figure 263 on page 384), the Figure 270 is displayed. On this panel, you can specify selection criteria for reporting on IP Network access configuration data. When you run the report, the results include only the records that match the selection criteria specified on the IP stack Selection panel and on this panel.

```
 Menu         Options       Info    Commands     Setup
------------------------------------------------------------------------------
                        zSecure Suite - IP stack - selection
Command ===> ____________________________________________________________

Show netaccess data that fit all of the following criteria:
IP address  . . . . . . ____________________________________________
RACF profile name   . . ____________________________________________
SAF resource name   . . ________________  (resource name or filter)
Check requests  . . . . _  1. Inbound  2.  Outbound  3.  Both
```

Figure 270. IP stack - selection - netaccess

For a description of the selection fields and to determine whether a field supports filters, use the field-sensitive help function (F1). See "IPNETACC - Communications Server IP netaccess display report" on page 495 for more information about the IP_NETACC report.

IP stack AUTOLOG configuration data - Specifying selection criteria

When you select the **AUTOLOG** option on the Resource - IP stack Selection panel (Figure 263 on page 384), the Figure 271 on page 389 is displayed. On this panel, you can specify selection criteria for reporting on IP stack AUTOLOG configuration data. When you run the report, the results include only the records that match the selection criteria specified on the IP stack Selection panel and on this panel.

```
 Menu         Options       Info    Commands     Setup
-------------------------------------------------------------------------------
                        zSecure Suite - IP stack - selection
Command ===> ____________________________________________________________

Jobname . . . . . . . . ________  (jobnname or filter)
Procname  . . . . . . . ________  (procnname or filter)
```

Figure 271. IP stack - selection - AUTOLOG

For a description of the selection fields and to determine whether a field supports filters, use the field-sensitive help function (F1). See "IPAUTOL - Communications Server IP autolog report" on page 496 for more information about the IP_AUTOLOG report.

IP stack resolver configuration data - Specifying selection criteria

When you select the **Resolver** option on the Resource - IP stack Selection panel (Figure 263 on page 384), an IP stack resolver configuration data report is generated. For more information about this report, see "IPRESOLV - Communications Server resolver report" on page 497.

Specifying output and run options

On the Resource - IP stack Selection panel (Figure 263 on page 384), you can use the Output/Run options to customize settings to run the report and generate output.

The output and run option settings you specify on the IP stack selection panels are saved in your ISPF profile and become the default settings for all IP stack panels that provide the option.

- To change the default setting on a panel, remove the selection from the field.
- To enable an option, enter an / in the input field for the option.
- If an option requires additional information and the information has not been specified, a panel opens so you can specify the information when you press Enter to run the query.
- If you select multiple options, the panels are presented in sequence until all required output and run parameters are specified.

Table 190 describes the available output and run options.

Table 190. Description of output and run options

Output/Run option	Description
Output in print format	Check this option to generate a printable report. When this option is selected, you can also use the options to customize the report title and send the report using email.
Customize title	Allows you to change the default report title. If you select this option, a panel is displayed so you can confirm or change the default report title. (See Figure 272 on page 390.) This option is only available when the **Output in print format** option is selected.

Table 190. Description of output and run options (continued)

Output/Run option	Description
Send as e-mail	If **Output in print format** is selected, you can select this option to send the report using e-mail. When you select this option, a panel opens where you can specify the e-mail information. Before configuring the e-mail information, you must configure the SMTP options with SETUP OUTPUT first. See "SE.7 Setup - Output" on page 1665.
Run in background	Determines whether the UNIX records processing is to proceed in the foreground or is to be submitted as a background (batch) job. This selection is only honored if Output in print format is also selected.

If you select the **Customize title** options, the panel shown in Figure 272 is displayed so you can specify the new titles.

Figure 273. Resource Unix Menu

Filesystem - Unix filesystem reports

This option can be used to select and display Unix file system records. A full `CKFREEZE` data set read is required, and the `CKFREEZE` data set must have been made with the `UNIX=Y` parameter. If the zSecure Collect run was APF-authorized, additional information is displayed.

When you select option RE.U, the Resource - Unix Selection panel shown in Figure 274 on page 391 opens.

```

```

Figure 274. Resource Unix selection panel

If the selection panel is left blank, all UNIX records are selected. You can limit the UNIX records selected by completing one or more fields to be used as selection criteria. Only records that match all criteria are selected. Filters can be used in some of the selection fields.

For a description of the selection fields and to determine whether a field supports filters, use the field-sensitive help function.

Advanced selection criteria

On the Resource - Unix Selection panel (Figure 274), you can select one of the Advanced selection criteria to specify filters to select and display Unix filesystem records. When you select a criteria, a panel opens where you can specify the attributes in which you are interested. Information about each Advanced Selection criteria option is provided in the following sections.

File attributes: Selecting the check box on the Resource - Unix Selection panel (Figure 274) opens the panel shown in Figure 275 on page 392 where you can specify the file attributes you are interested in.

See the online help for detailed field descriptions.

     _  Directory has a directory default access list
     _  File or directory has an extended access list
```

Figure 277. Resource Unix ACL selection panel

Output/Run options

On the Resource - Unix Selection panel (Figure 274 on page 391), you can use the Output/Run options to customize settings to run the report and generate output.

The output and run option settings you specify on the Unix selection panels are saved in your ISPF profile and become the default settings for all Unix panels that provide the option.

- To change the default setting on a panel, remove the selection from the field.
- To enable an option, enter an / in the input field for the option.
- If an option requires additional information and the information has not been specified, a panel opens so you can specify the information when you press Enter to run the query.
- If you select multiple options, the panels are presented in sequence until all required output and run parameters are specified.

Table 191 describes the available output and run options.

Table 191. Description of output and run options

Output/Run option	Description
Output in print format	Check this option to generate a printable report. When this option is selected, you can also use the options to customize the report title and send the report using e-mail.
Customize title	Allows you to change the default report title. If you select this option, a panel is displayed so you can confirm or change the default report title. This option is only available when the **Output in print format** option is selected.
Send as e-mail	If **Output in print format** is selected, you can select this option to send the report using e-mail. When you select this option, a panel opens where you can specify the e-mail information. Before configuring the e-mail information, you must configure the SMTP options with SETUP OUTPUT first. See “SE.7 Setup - Output” on page 1665.
Run in background	Determines whether the UNIX records processing is to proceed in the foreground or is to be submitted as a background (batch) job. This selection is only honored if Output in print format is also selected.

Unix records display

After processing the CKFREEZE file, the UNIX summary panel opens to display the results as shown in Figure 278.

Figure 278. Unix summary display

The following table describes the fields of interest on the UNIX summary panel.

Table 192. UNIX summary panel - fields of interest

Field	Description
Complex	The complex name.
System	The system name.
Count	The total number of files in the file system.
FS mount point	The directory where the file system is mounted.

Viewing UNIX files for a selected mount point: Selecting any of the mount points listed in the UNIX summary panel (Figure 278) displays the list of UNIX files for that mount point as shown in Figure 279.

You can perform the following actions from the UNIX file list display panel:

- Enter **B** to browse the regular files.
- Enter **I** for a file or directory to call the UNIX System Services ISPF Shell
- For directories, enter the **U** action command to start the z/OS UNIX Directory List Utility

The following table provides the field descriptions for the UNIX file list display.

Table 193. UNIX file list display - fields of interest

Field	Description
T	File type. This field can have any of the following values: **-** regular file **b** block special file **c** character special file **d** directory **e** external symlink **l** symlink **p** pipe **s** socket
Filemode	The effective file mode, shown as lists of permissions for specific groups. The groups can be any of the following: *o* owner *g* group *o* other An *a* indicates that the permissions of all groups are equal. The permissions can be any of the following: *r* read *w* write *e* execute *s* setup/setgid *S* setup/setgid when execute permission is off *t* sticky bit *T* sticky bit when execute permission is off Note that this format is the same as used by the `chmod` command.

Table 193. UNIX file list display - fields of interest (continued)

Field	Description
+	Indicates whether a file has any (extended) ACL entries; these can be any of the following types of entries: access directory default file default
apse	The effective extended attributes, shown as a list of attributes that are on (+) and a list of attributes that are off (-). Attributes can be any of the following: *a* authorization *p* program controlled *a* address space sharing *l* library sharing An *a* indicates that the permissions of all groups are equal. The permissions can be any of the following: *r* read *w* write *e* execute *s* setup/setgid *S* setup/setgid when execute permission is off *t* sticky bit *T* sticky bit when execute permission is off Note that this format is the same as used by the `chmod` command.
AuF	The combined audit flags: three positions for read, write, and execute access. Each position indicates the audit flag setting which can be any of the following: *s* successes *f* failures *a* all - none *Combined* either the owner or auditor has requested auditing
Owner	The RACF `userid` that is mapped to the owning UID. If there are several such RACF user IDs, this is the alphabetically first one.
Relative pathname (within FS)	Path name relative to the file system's mount point.

Viewing UNIX file details: When you browse a file from the UNIX file list display panel shown in Figure 279 on page 394, the UNIX file detail display panel shown in Figure 280 on page 397 opens. To browse the contents of a file in this panel, type **B** in front of the **Absolute pathname** field.

Figure 280. Unix detail display

For details on the fields available on this display, see the following sections.

- "System view of file" on page 398
- "Physical file attributes" on page 399
- "UNIX access lists" on page 400

System view of file: This section shows the effective settings. For example, the absolute `pathname` consists of the relative `pathname` within the HFS or zFS data set, prefixed by the mount point of the file system. The effective flags take the mount attributes and mode into account.

Table 194 lists the fields available in this section.

Table 194. UNIX file detail display - System view of file fields

Field	Description
Complex name	The complex name.
Sysplex name	The sysplex name.
System name	The system name.
Absolute pathname	The full path name for the file. To view the contents of the file, type **B** in this field.
FS mounted with SECURITY	Whether the file system is mounted with the SECURITY attribute. If not, any user can access and change any file in it.
FS mounted with SETUID	Whether the file system is mounted with the SETUID attribute. Setuid, setgid, APF, and program control attributes are only honored when the file system is mounted.
FS mounted READ/WRITE	The mode in which the file system is mounted: READ The file system is mounted read-only; RDWR The file system is mounted read/write.
File access attributes	The effective file mode, shown as lists of permissions for specific groups. The group type is indicated by any of the following values. *o* for owner *g* for group *o* for other *a* for all The permissions can be *r* read *w* write *e* execute *s* setuid and setgid *t* sticky bit (setuid is shown with *u*, setgid with *g*).
Security label	The security label for the file.
Extended file attributes	The effective extended attributes, shown as a list of attributes that are on (+) and a list of attributes that are off (-).
Effective audit flags	The effective audit flags, shown as lists of the following values, or as a single list if the access type does not matter. *f* failures *s* successes for the access types *r* read, *w* write *x* execute
Owner name	The RACF `userid` that maps to the UID for the file. If there are more such users, a list is shown.
Group name	The RACF group that maps to the GID for the file. If there are more such groups, a list is shown.

Table 194. UNIX file detail display - System view of file fields (continued)

Field	Description
Home Directory	This repeated field can only be filled in for a directory. It lists the users for whom this directory is their home directory.
Device	The device number identifying the mount point.
Relative audit priority	The audit priority for this file.
Audit concern	The audit concerns identified for this file. See "UNIX: UNIX System Services File System" on page 1480 for a list of the audit concerns that can be identified.

Physical file attributes: This section shows the physical characteristics, such as the flags actually indicated in the file system itself.

Table 195. UNIX file detail display - Physical file attributes fields

Field	Description
Complex that owns file system	Complex of the system that owns the file system.
System that owns file system	System that owns the file system.
File system data set name	The name of the data set that holds the file system.
Volume serial for file system	The volume serial of the HFS or zFS data set.
File system DASD serial + id	Manufacturer/Factory/Serial identifying the DASD, and device tag id (port) assigned to this volume on the owning system.
Relative pathname within FS	Path name relative to the file system's mount point.
File type	The type of file. The UNIX file types are: *-* regular file *d* directory *p* pipe (or FIFO) *b* block special file *e* external symlink *s* socket *c* character special file *l* symlink.

Table 195. UNIX file detail display - Physical file attributes fields (continued)

Field	Description
Physical access attributes	The physical file mode shown as lists of permissions for specific groups. The group type is indicated by the following values: *o* for owner *g* for group *o* for other *a* for all The permissions can be *r* for read *w* for write *x* for execute *s* for set gid *u* for sticky bit setuid *g* for sticky bit setgid
Physical extended attributes	The physical extended attributes, shown as a list of attributes that are on (+) followed by a list of attributes that are off (-).
User-requested audit flags	The audit flags requested by the owner, shown as lists of the following values, or as a single list if the access type does not matter. *s* successes *f* failures *r* read *w* write *x* execute
Auditor-specified audit flags	The audit flags specified by the auditor, shown similarly.
User id	The UID for the file.
Group id	The GID for the file.
Inode number	The inode number for the file. This number identifies the file within the file system.
File audit id	The audit ID for the file.
Number of hard links	The number of directory entries for the file. Note that a UNIX file has no canonical path name; the inode identifies a file within the file system. File and other attributes are associated with the inode, not the path name.

UNIX access lists: Shows the UNIX access lists. An access ACL can be shown for any file type. For a directory, a directory default and a file default ACL can also be shown.

The UNIX access control list contains the following fields.

Table 196. UNIX file detail display - Access control list fields

Field	Description
User	The user to which the entry pertains. This field can show any of the following values: • *-group-* in an unexpanded ACL (or in an exploded ACL, for an empty group); in that case the **ACL id** field shows the group • *-undef-* in an unexpanded or exploded ACL for a UID or GID that does not correspond with a RACF user or group (as appropriate). • *-any-* shows the global access setting.
TOrwx	This field indicates the ACL type, origin, and user access permissions: ACL Type (**T**) can be any of the following: *d*directory default *f* file default blank access + ACL entry *a* auditor attribute *r*, *w*, *x* indicates the user access; read, write or execute ACL entry Origin (**O**) can be any of the following: *u* owning user *g* owning group *o* other User access permissions *r* read access *w* write access *x* execute access
ACL id	A RACF user or group associated with the UID/GID. This column can show a RACF user or group, or special origin values *-other-* for the global access setting (User *-any-*), *-owner-* for a file owner UID *-group-*for an owning group GID *-ACLuid-* for a UID on the ACL *-ACLgid-* for a GID on the ACL *-audit-* for directory read/execute access through the system-wide AUDITOR attribute *-more-* when an actual access level has more than one origin.

Table 196. UNIX file detail display - Access control list fields (continued)

Field	Description
UID/GID	The UID or GID that grants this access or an indication why none applies. If the column shows a number, this is a UID if **User** and **ACL id** are equal (if a RACF identity was determined), and also if **ACL id** contains *-owner-* or *-ACLuid-* (if not). Otherwise it is a GID. This column shows *n/a* for the global access setting (User *-any-*), for a composite entry (ACL id *-more-*), or when r-x access to a directory is granted to a user on the basis of the RACF auditor attribute. In an exploded ACL, this column can show *-no uid-* or *-no gid-* for RACF auditor user that has no access to UNIX because there is no associated GID or UID, either directly or through BPX.DEFAULT.USER.
Name	The user name.
InstData	The installation data for the user or group.

CICS resource reports

The **RE Resource reports** option on the zSecure Audit Main menu shown in Figure 262 on page 383 allows you to select and display CICS region, transaction, and program data. The report data is obtained from a CKFREEZE data set that is created by running zSecure Collect APF-authorized.

Select **RE.C** from the zSecure Audit Main menu to display the CICS Resource panel shown in Figure 281.

The **T** and **P** options are features provided by the zSecure Audit products.

```
Menu         Options       Info    Commands     Setup      Startpanel

CICS region reports

In the CICS Resource panel in Figure 281, select the **R** menu option to display the CICS Regions selection panel in Figure 282 on page 403.

Use this panel to enter selection criteria in one or more fields to limit the CICS region configuration data. When you specify selection criteria, the output includes only those records that match all the selection criteria. Filters can be used in some of the selection fields. To find out if a field supports filters, use the field-sensitive help function (F1).

You can also select output and run options in the CICS Regions selection panel, or select no options and report data is processed as soon as you press Enter. The overview panel that is displayed shows a summary of the CICS region records that

match your selection criteria.

Figure 285. CICS Regions classes

In Figure 286 on page 405, the CICS region display report lists the CICS region configuration settings.

The data for the region display report is available only if a CKFREEZE file is created during an APF-authorized run of zSecure Collect (the CKFCOLL program). For details about creating a CKFREEZE file, see Chapter 16, “zSecure Collect for z/OS,” on page 1591.

Detailed field information is available by pressing F1 on the CICS regions display panels or on any field in the display panels. Descriptions of CICS region field names are also provided in “CICS_REGION: CICS regions” on page 974.

A sample overview display panel for the CICS regions display report is shown in Figure 286 on page 405.

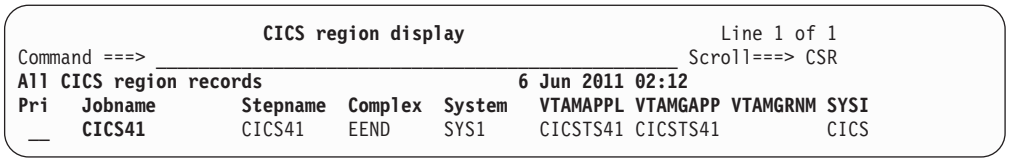

Figure 286. CICS region overview display report

Figure 287. CICS region detailed display report

CICS transaction reports

In the CICS Resource panel in Figure 281 on page 402, select the **T** menu option to display the CICS Transactions selection panel in Figure 288.

Use this panel to enter selection criteria in one or more fields to limit the CICS transaction data. When you specify selection criteria, only those records that match all criteria are included in the output. Filters can be used in some of the selection fields. To find out if a field supports filters, use the field-sensitive help function (F1).

To create a simulate report, use the report type option **Simulate access for specified resource**.

You can also select output and run options in the CICS Transactions selection panel, or select no options and report data is processed as soon as you press Enter. The overview panel that is displayed shows a summary of the CICS transaction records that match your selection criteria.

Figure 288. CICS Transactions selection panel

In Figure 288, you can select advanced selection criteria. When you select **Security settings**, the CICS Transactions security attributes panel in Figure 289 on page 408 is displayed.

In Figure 289 on page 408, the **RACF profile class** and **RACF profile name** fields select resources by using the merged in-storage profile built during the RACLIST process. If either the specified RACF profile class or the specified RACF profile name contributed to the in-storage profile, the resource is included in the report. The specified RACF profile name does not need to be defined in the specified RACF profile class for the resource to be included in the report.

Figure 295. CICS Programs attributes

In Figure 296, the CICS program display report lists the CICS program settings.

The data for this report is available if a CKFREEZE file has been created during an APF-authorized run of zSecure Collect (the CKFCOLL program). For details about creating this file, see Chapter 16, “zSecure Collect for z/OS,” on page 1591.

Detailed field information is available by pressing F1 on the CICS program display panels or on any field in the display panels. Descriptions of CICS program field names are also available in “CICS_PROGRAM: CICS programs” on page 970.

A sample overview display panel for the CICS program display report is shown in Figure 296.

Figure 298. IMS Resource panel

IMS region reports

In the IMS Resource panel in Figure 298, select the **R** menu option to display the IMS Regions selection panel in Figure 299.

Use this panel to enter selection criteria in one or more fields to limit the IMS region configuration data. When you specify selection criteria, the output includes only those records that match all the selection criteria. Filters can be used in some of the selection fields. To find out if a field supports filters, use the field-sensitive help function (F1).

You can also select output and run options in the IMS Regions selection panel, or select no options and report data is processed as soon as you press Enter. The overview panel that is displayed shows a summary of the IMS region records that match your selection criteria.

Figure 305. IMS region detailed display report

IMS transaction reports

In the IMS Resource panel in Figure 298 on page 414, select the **T** menu option to display the IMS Transaction selection panel in Figure 305.

Use this panel to enter selection criteria in one or more fields to limit IMS transaction data. When you specify selection criteria, only those records that match all criteria are included in the output. Filters can be used in some of the selection fields. To find out if a field supports filters, use the field-sensitive help function (F1).

To create a simulate report, use the report type option **Simulate access for specified resource**.

You can also select output and run options on the IMS transaction selection panel, or select no options and report data is processed as soon as you press Enter. The overview panel that is displayed shows a summary of IMS transaction records that match your selection criteria.

Figure 311. IMS PSB security attributes

In Figure 312, the IMS PSBs display report lists the IMS PSB settings.

The data for this report is available only if a CKFREEZE file is created during an APF-authorized run of zSecure Collect (the CKFCOLL program). For details about creating this file, see Chapter 16, "zSecure Collect for z/OS," on page 1591.

Detailed field information is available by pressing F1 on the IMS PSB display panels or on any field in the display panels. Descriptions of IMS PSB field names are also available in "IMS_PSB: IMS program specification blocks" on page 1039.

A sample overview display panel for the IMS PSBs is shown in Figure 312.

Figure 312. IMS PSB overview display panel

A sample detail display panel for the IMS PSB display report is shown in Figure 313 on page 422.

The **Class** and **Profile** fields show the grouping and member class profiles that contributed to the merged in-storage profile for the resource as established during the RACLIST process. The access list that follows shows the access to this merged in-storage only profile. The display format of the access list can be managed using the ACL primary command.

DB2 resource reports

The **RE Resource reports** option on the zSecure Audit Main menu shown in Figure 262 on page 383 allow you to select and display DB2 region data.

Select **RE.D** from the zSecure Audit Main menu to display the DB2 regions selection panel shown in Figure 314 on page 423.

DB2 region reports

Use this panel to enter selection criteria in one or more fields to limit the DB2 region configuration data. When you specify selection criteria, the output includes only those records that match all the selection criteria. Filters can be used in some of the selection fields. To find out if a field supports filters, use the field-sensitive help function (F1).

You can also select output and run options in the DB2 regions selection panel, or select no options and report data is processed as soon as you press Enter. The overview panel that is displayed shows a summary of the DB2 region records that match your selection criteria.

Chapter 5. System Audit Guide

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The system audit reports for monitoring z/OS using zSecure can be generated from

- "Interactive component zSecure Audit for RACF" explains how to start zSecure under ISPF and view system reports.
- "STATUS AUDIT - OVERVIEW" on page 430 describes the Status Audit Overview report.
- "STATUS AUDIT - MVS tables" on page 440 describes the system report types that do not require a full `CKFREEZE` data set read.
- "STATUS AUDIT - MVS extended tables" on page 499 describes the system report types that require a full `CKFREEZE` data set read.
- "AU.C Change track" on page 521 explains how to use the Change Track function to monitor changes in the security settings.
- "Batch auditing" on page 525 describes several ways to use zSecure for batch-only reporting.
- "Predefined CARLa scripts" on page 525 discusses the interactive ISPF and batch reports available in the SCKRCARL library.

Interactive component zSecure Audit for RACF

This section describes the system report types. Each report type description provides background information and report samples. See the following sections for more information:

- To start the product, see "Starting the interactive component" on page 9.
- For details on the zSecure ISPF panels, see "Panel structure" on page 10.

After you start the product, select the Audit option (AU) from the Main menu to open the Audit menu shown in Figure 318 on page 426.

5655-T02 IBM Security zSecure Audit for RACF 1.13.0
```

Figure 318. zSecure Audit for RACF Main menu

This section of the documentation focuses on Audit functions. For more information on the Audit menu options, refer to the sections indicated in Table 197. For a table of references for the other main menu options like Events (EV) and RACF Administration (RA), see "Panel structure" on page 10. You can also find information about the panels and fields by using the context-sensitive help function available on most panels. To access the help, press PF1 or type HELP.

Table 197. Documentation references for Audit Menu options

Audit menu option	Documentation reference
AU.S Audit status	"STATUS AUDIT - OVERVIEW" on page 430 and "STATUS AUDIT - MVS tables" on page 440
AU.S, **RA** and **AU.V**	Information on the part of **AU.S** that pertains to a RACF audit and the menu options **RA** RACF and **AU.V** Verify is available inChapter 3, "RACF Audit Guide," on page 255.
AU.C Change Track	"AU.C Change track" on page 521
AU.L Libraries	Chapter 6, "Library Audit Guide," on page 529

The STATUS AUDIT application (option **AU.S** from the main menu) shows the contents of MVS and RACF security tables and settings. The first menu is displayed in Figure 319.

```
  Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                          zSecure Audit - Audit - Status
Command ===> ____________________________________________________________
Enter / to select report categories
/    MVS tables      MVS oriented tables (reads first part of CKFREEZE)
/    MVS extended    MVS oriented tables (reads whole CKFREEZE)
_    RACF control    RACF oriented tables
_    RACF user       User oriented RACF tables and reports
_    RACF resource   Resource oriented RACF tables and reports

 Select options for reports:                                    Audit policy
 _   Select specific reports from selected categories          /  zSecure
 /   Include audit concern overview in overall prio order      _  C1
 _   Only show reports that may contain audit concerns         _  C2
 __   Minimum audit priority for audit concerns (1-99)        _  B1
 _   Print format              _  Concise (short) report
     _  Background run
```

Figure 319. Audit status menu

The available reports are divided into a number of categories. The first two, MVS TABLES and MVS EXTENDED, contain the pure MVS reports. The reports in the first category do not require a full CKFREEZE read, but the reports in the second category do. In addition, the RACF RESOURCE category contains a couple of reports that pertain mostly to MVS, but use RACF-specific knowledge on the protection of sensitive data sets, the protection of APF modules, the definition of started tasks, the relationship between RACF users and groups and z/OS UNIX UIDs and GIDs. The MVS categories are described in this chapter. The RACF categories are described in Chapter 3.

You can select categories by marking them with a '/'.

The panel allows you to specify the following processing parameters:

Select specific reports from selected categories
If you select this option, you will get a follow-up panel for each selected category where you can select the desired reports. If you do not select this option, all reports in the selected categories are generated.

Include audit concern overview in overall prio order.
This option determines whether an audit concern overview is generated. This overview shows up as the first item in the output. It is sorted by audit priority, and contains a single line for each item for which audit concerns were identified, including an indication of which report the item occurs in. Note that not all reports explicitly identify audit concerns; they are not represented here. The overview spans the categories selected (not just the selected reports). If you select this option without selecting any categories, an overview for all categories is generated. If you only want an overview across a specific category, you can select that category along with the *Select specific reports from selected categories* option, but not select any of the reports.

Only show reports that may contain audit concerns
If you select this option, only the reports that can contain audit concerns are displayed. If *Select specific reports from selected categories* is also requested, only the reports that can contain audit concerns are selectable.

Minimum audit priority for audit concerns (1-99)
Specify the minimum audit priority for audit concerns or leave blank for all records.

Print format
For a foreground run, selecting this option requests to present the output in a printable report format instead of as interactive displays. This is preferable if memory is tight or the output is to be printed. For a detail study of a small amount of data, the interactive display format is generally better suited. For a background run, this option has no effect.

Concise (short) report
Leave out detailed information from the generated reports. Use this option to review changes or explore the system. Do not use this option if you must have comprehensive audit information.

Background run
Submits a background (batch) job for generating the selected reports in print format. Selecting this option also implies that Print format is selected for the output. If you do not select this option, report processing runs in the foreground.

Audit policy
Select the audit policy for determining the audit concerns and priorities. The default audit policy raises the concern priority to 40 or more if it is likely that the system could almost certainly be compromised because of it. The *C1*, *C2*, and *B1* selections refer to the DoD orange book standards; these will also set priorities to 40 or more when a violation of the selected policy is noticed. It is not implied that all violations will be noted. In addition, *B1* will generate more audit concerns.

When running in foreground, Security zSecure displays the number of RACF and CKFREEZE records read during processing. After processing, the resulting output is displayed. Processing can be halted by pressing the ATTN key.

When you select certain reports, an additional panel opens for customizing the report. If you are running the reports for the first time to get a general overview, you can leave this panel blank.

When you have selected a set of system reports without selecting either *Output in print format* or *Run in background* , Security zSecure runs immediately and generates a report selection display showing the selected report information.

The contents of this display will of course vary with the report options selected. A sample report selection display is included in Figure 320 on page 429.

Figure 320. MVS Security report selection display

The preceding reports are based on the MVS system. They are described in this chapter. The reports based on RACF are described in Chapter 3.

zSecure Audit for RACF assigns a numerical *audit priority* to each system report entry, indicating the need to review the entry. Higher numbers indicate greater concern; numbers 20 and up require review, numbers 40 and up require immediate attention. In addition to the audit priority field each report entry also has an audit concern field which in case of a found concern describes the reason for the concern.

Figure 321. MVS Security audit overview display

STATUS AUDIT - OVERVIEW

The OVERVIEW report at the top of the selection list is a good point to start a system audit. The report summarizes the most important audit concerns across all report types and all systems audited, sorted by numerical audit priority. A pointer to the relevant report type is included. We suggest you view this report first, and then explore the other reports, starting with the reports having the highest audit priority. Figure 322 shows an audit overview display.

Figure 322. MVS Security audit overview display

The overview report contains the following fields of interest:

Table 198. Audit concern overview by priority - field descriptions

Field	Explanation
Pri	Numerical audit priority, identifying the severity of the problem. Priorities of 40 and up indicate a very serious concern, requiring immediate attention. Priorities in the range 20 to 39 require review because serious security threats might exist.
Complex	The name of the complex to which the system belongs on which audit concerns were identified.
Syst	The name of the system on which the audit concern was identified.
Area	The report type in which the audit concern was identified.
Key	The report key identifying the entry within the relevant report. The value and meaning of the key is report dependent.
Audit concern	The audit concern identified. Background information on the reason for the concern.

The table lists the abbreviations and the NEWLIST types for the various report types. The page numbers refer to the audit concern sections.

Table 199. NEWLIST type abbreviations listed by report type

Abbreviation	Report type	NEWLIST type
CLAS	Class Descriptor Table	CLASS (page 990)
CONS	Console	CONSOLE (page 1004)
DASD	DASD volume	DASDVOL (page 1013)
DMS	SAMS:Disk parameters	AUDIT (page 961)
EXIT	Exit	EXIT (page 1029)
FILE	UNIX files	UNIX (page 1481)
HSM	Hierarchical Storage Manager	AUDIT (page 961)
IOAP	I/O appendage	IOAPP (page 1052)
IP	IP stack	IP_STACK (page 1075)
IPRE	IP resolver	IP_RESOLVER (page 1066)
JCL	JES2 job class	JOBCLASS (page 1090)
MOUN	UNIX Mount Points	MOUNT (page 1104)
MSG	Message Processing Facility	MSG (page 1107)
MVS	MVS properties	AUDIT (page 961)
PC	Program Call	PC (page 1113)
PORT	IP port	IP_PORT (page 1061)
PPT	Program Property Table	PPT (page 1122)
RACF	RACF profiles	RACF (page 1131)
ROUT	SAF router table	ROUTER (page 1250)
SENP	Sensitive profiles	REPORT_SENSITIVE (page 1242)
SENS	Sensitive data sets	SENSDSN (page 1256)
SETR	SETROPTS settings	AUDIT (page 961)
SMF	SMF system settings	AUDIT (page 961)
SMFO	SMF subsystem	SMFOPT (page 1403)
SSCT	Subsystem	SUBSYS (page 1407)
STOR	Writable common storage	CSM (page 1009)
SVC	SuperVisor Call	SVC (page 1417)
SYSL	Syslog settings	AUDIT (page 961)
TRUS	Trusted users and sensitive resources	(page 1476)
TSO	TSO settings	AUDIT (page 961)
VM	VM properties	AUDIT (page 961)
VSM	Virtual storage map	VSM (page 1493)

Each of these types is described in this guide. See Chapter 3, “RACF Audit Guide,” on page 255 for a description of CLAS, FILE, RACF, SENP, SETR and TRUS.

If you select one of the audit concerns listed with the **S** action character, a detail display is shown.

```
Audit concern overview by priority (higher priorities only)       Line 1 of 17

Figure 323. Detail display layout (for an SVC concern)

The detail display layout depends on the report type in which the audit concern was identified, the preceding example shows the layout for an SVC concern.

The detail display repeats the following report-independent fields of interest (in full):

Table 200. Audit concern overview by priority detail view - field descriptions

Field	Explanation
Complex name	The complex name
System name	The system name
Relative audit priority	The severity of the concern
Audit concern	The audit concern identified

The detail display also contains a report-dependent section, containing the fields mentioned in the following tables. See Chapter 3, "RACF Audit Guide," on page 255 for the explanation of CLAS, FILE, RACF, SENP, SETR, and TRUS details.

Table 201. Audit concern overview by priority detail view - Console report field descriptions

Field	Explanation
Console number	The console number.
Console name	The console name.
Device number	The console's device number. This field is not present for subsystem consoles.
Job or subsystem name	The subsystem the console is dedicated to, or the jobname for EMCS consoles. In other cases, this field is blank.
Console logon	The system-wide setting that determines whether logon is required to use a console. It can be *OPTIONAL*, *REQUIRED*, or *AUTO*.
User logged on to console	The user ID logged on to the console. This field is blank if no one is logged on to the console (when the previous field shows *OPTIONAL*).

Table 201. Audit concern overview by priority detail view - Console report field descriptions (continued)

Field	Explanation
Command authority	Indicates the types of commands that can be issued from the console. This field can have one or more of the following values: *SYS* (system) *IO* (I/O) *CONS* (console) *MASTER* (master console) *INFO* (informational) *ALL* (all of these)
Undirected messages	Whether this console accepts undirected messages.
Routing codes	The routing codes for this console.
Message level	The kind of messages the console accepts. It can contain any combination of the following values: • *R* (requiring operator reply) • *I* (immediate action) • *CE* (critical event) • *E* (event) • *IN* (informational) • *NB* (no broadcasts) • *ALL* (all of these)
Alternate console name	The name of the alternate console (if any). On older MVS releases (earlier than SP4.1) this field contains the device number of the alternate console instead of its name.

Table 202. Audit concern overview by priority detail view - DASD volume report field descriptions

Field	Explanation
Volume serial	The DASD volume's volume serial number.
DASD box serial number and id	The box serial number consisting of manufacturer id, factory id and serial number, plus the device id associated with it.
DASD box type	The DASD type, followed by the model.
Number of systems mounted	The number of systems that the volume is mounted on.

Table 203. Audit concern overview by priority detail view - SAMS:Disk field descriptions

Field	Explanation
Parameter name	The SAMS:Disk parameter
Parameter value	The value the parameter is set to.

Table 204. Audit concern overview by priority detail view - Exits and table field descriptions

Field	Explanation
Application owning exit	The application or subsystem owning the exit.

Table 204. Audit concern overview by priority detail view - Exits and table field descriptions (continued)

Field	Explanation
SMF subsystem using exit	The subsystem name (when the previous value was JES2).
Name of the dynamic exit	Full name if it is a dynamic exit, blank otherwise.
Function of the exit	A description explaining the exit's function.
Exit program name	The documented program name of the exit or table.
Jobname of exit address space	The jobname of the address space the exit resides in, if in (E)PVT.
Exit address at	A description of program name or module name, and offset.
Address called for the exit	For an exit the entry point, for a table its start address.
Exit length	The length of the program/module the exit is a part of
Exit residency	The virtual storage area where the exit resides.
Exit storage area key	The storage protection key of the exit or table.
Exit storage area subpool	The storage area subpool, if in (E)CSA or (E)SQA.

Table 205. Audit concern overview by priority detail view - HSM / MVS / SMF / SYSL / TSO - System settings field descriptions

Field	Explanation
Parameter area	The area of concern: HSM (Hierarchical Storage Manager), MVS, SYSLOG (system log), SMF (audit log), or TSO.
Parameter name	The system parameter.
Parameter value	The value it is set to.

The report type "SMF" can also refer to the "SMF subsystem" report. See “SMFSUBOP - SMF subsystem report” on page 446.

Table 206. Audit concern overview by priority detail view - I/O appendage (IAOP) field descriptions

Field	Explanation
Appendage ID	The id of the authorized I/O appendage.
Appendage type	The I/O appendage is one or more of the following types: *ABE* (abnormal end), *CHE* (channel end), *EOE* (end of extent), *PCI* (program controlled interrupt), *SIO* (start I/O).
Conforms to default	Whether the types enumerated above accord to the IBM default
Appendage description	A description of the function of the I/O appendage.
Module name loaded by OPEN	The full name of the I/O appendage (always starts with IGG019).
Entry point if resident	The address in-storage, if loaded.

Table 206. Audit concern overview by priority detail view - I/O appendage (IAOP) field descriptions (continued)

Field	Explanation
Appendage residency	The virtual storage area where the appendage resides

Table 207. Audit concern overview by priority detail view - IP port report field descriptions

Field	Explanation
Beginning port	The first port in a range of reserved ports.
End port	The last port in a range of reserved ports.
Bind IP address	The IP address associated with the job name present in the JOBNAME field.
Port use restriction	An indication of how the port is used.
Port count	The number of ports in a range of reserved ports.
Port options	Information about the current status of IP interface settings.
PORTRANGE entry	Indication whether a PORTRANGE statement was used.
Protocol	The protocol associated with a range of ports.
Secure unreserved ports	Indication whether a PORT UNRSV statement was used.
SERVAUTH resource name	The name of a SAF SERVAUTH resource.

Table 208. Audit concern overview by priority detail view - IP resolver report field descriptions

Field	Explanation
Stack name	The member name of the procedure used to start the TCP/IP address space.
Host name	The TCP host name of the z/OS CS server.
Setup file	The name of the resolver setup file name (either an MVS data set or a z/OS UNIX file) that contains resolver configuration statements.
Default TCPIP.DATA file	The name of either a z/OS UNIX file or MVS data set with TCPIP.DATA statements that is the last file that is searched by the resolver for resolver configuration information.
Global TCPIP.DATA file	The name of either a z/OS UNIX file or an MVS data set containing the statements that define the global TCPIP.DATA settings for the entire MVS image and for all TCP/IP stacks.
Default IPNODES file	The name of either a z/OS UNIX file or MVS data set that contains the hard-coded IP addresses and host names to be used.
Global IPNODES file	The name of either a z/OS UNIX file or MVS data set that contains hard-coded IP addresses and host names that are used globally.

Table 209. Audit concern overview by priority detail view - IP stack report field descriptions

Field	Explanation
Stack name	The stack name which is the name of the started task procedure running the stack.

Table 209. Audit concern overview by priority detail view - IP stack report field descriptions (continued)

Field	Explanation
TCP low ports restricted	Flag field that indicates whether TCP ports 1 to 1023 are reserved for users by the PORT and PORTRANGE statements.
UDP low ports restricted	Flag field that indicates whether UDP ports 1 to 1023 are reserved for users by the PORT and PORTRANGE statements.
Start date/time	The date and time that the TCP/IP stack was started.
Last change date and time	The date and time that the TCP/IP stack was last changed.
Dataset name (member)	This repeated field contains an entry for each profile information data set name followed by a member name between brackets: [membername]. The data set name entries can originate from the following sources: an OBEYFILE command, the default library found in the standard search sequence, or an INCLUDE statement.
TCP/IP stack source VIPA	The IPv4 address used as the source IP address for outbound TCP connections.
VIPA interface name (IPv6)	The name of a static VIPA or a dynamic VIPA interface.

Table 210. Audit concern overview by priority detail view - JES2 job class (JCL) field descriptions

Field	Explanation
Subsystem name	The name of the subsystem.
Job class	The class name (a single character).
Command disposition	The action taken for MVS commands embedded in JCL: DISPLAY (display on the console and execute without verification), EXECUTE (execute without display or verification), IGNORE (silently ignore the command), or VERIFY (have the operator verify the command).
Authorized command groups	The MVS command groups to be executed: any combination of SYS (system), IO (I/O), CONS (console) and INFO (informational), or ALL (all of these).
Bypass Label Processing	Whether the bypass label parameter in the label field of a DD parameter is performed subject to SAF controls (vs. ignored entirely).
Jobs held until released	Whether jobs in this class are held until the operator issues a RELEASE.

Table 211. Audit concern overview by priority detail view - UNIX mount points (MOUN) field descriptions

Field	Explanation
Mount point	The absolute pathname of the mount point
Unix device number	The device number as assigned when the file system is mounted.
File system mode	The mode in which the file system is mounted: READ (read only) or RDWR (read/write)
File system type	The type of the file system (AUTOMNT,TFS,HFS,ZFS,.....)

Table 211. Audit concern overview by priority detail view - UNIX mount points (MOUN) field descriptions (continued)

Field	Explanation
File system name	The name of the file system.
Mounted with security	Whether the file system is mounted with the security attribute. If not, any user can access and change any file in it.
Mounted with SETUID	Whether the file system is mounted with the SETUID attribute. If not setuid, setgid, APF and program control attributes are not honored.
File system supports ACLs	Whether the filesystem supports access lists.
New block security	Whether blocks that are allocated are cleared before they are linked.
Owning complex	The complex the "Owning system" is in.
Owning system	The system that owns the file system.
Data set name	The name of the MVS data set that contains the file system.
Volume serial	The volume serial that holds the MVS data set.
DASD box serial number and ID	The serial code of the volume containing the code of the manufacturer, factory code, box serial number, and device tag.
Size of block in bytes	Size of a block of the zFS file system in bytes (normally 8192).
Size of fragment in bytes	Size of a fragment of the zFS file system in bytes. Multiple files can share a logical block if they are smaller than (block size - fragment size), in which case the block gets split up in fragments. The size of a fragment can range from 1024 up to the block size.
Size of aggregate in blocks	The size in blocks of the aggregate. Normally the number of blocks that fit in the primary allocation.

Table 212. Audit concern overview by priority detail view - Message Processing Facility (MSG) field descriptions

Field	Explanation
Message id	The message id
Suppress message	Whether the message is suppressed.
Automation for messages	Whether the message is automated; if so, and if an automation token was defined, that token is shown.
Parmlib member	The parmlib member used to set MPF processing for this message.
Exit name	The module name of a user exit for this message (if any).
Exit address	The address of the user exit.
Exit residency	The virtual storage area where the exit resides.
Exit load module information	The program name, module name and offset for the exit.

Table 213. Audit concern overview by priority detail view - Program call (PC) field descriptions

Field	Explanation
Entry Table owning jobname	The jobname of the address space owning the Entry Table.
Entry Index	The index in the Entry Table that identifies the program call routine
Function Description	If system-wide, a description of the entry in the System Function Table. Otherwise, the value might contain the best guess for the description as determined by Security zSecure processing based on the module name. If the value represents a guess, it is enclosed in brackets to indicate uncertainty.
Authority required	Whether authority (not key 8) is required to call the routine.
PC routine residency	The virtual storage area where the program call routine resides.
Program Call entry point at	The program name, module name and offset for the program call routine.

Table 214. Audit concern overview by priority detail view - Program Property Table (PPT) field descriptions

Field	Explanation
Program name (must be APF)	The program name that gets properties assigned (if APF)
Job step storage key	The key in which the program runs (if assigned); key 0 to 7 imply system authorization
Bypass password / SAF	Whether DFSMS will bypass invoking SAF for security checks by the External Security Manager (RACF).
No data set integrity	Whether no enqueues are done for data sets in the batch. If enqueues are not done, it might cause problems with data management procedures that result from a data set being removed while it is being used.
Default entry IEFSDPPT	Whether this entry comes from the default module IEFSDPPT, and not from SCHEDxx.
Non-swappable	Whether the program is non-swappable.
Non-cancellable	Whether the program cannot be cancelled with a CANCEL command.
Privileged (no SWAP)	Whether the program runs privileged; if so the program is not swapped unless it is in a long wait state.
System task not timed	Whether the program is a system task, and not timed.

Table 215. Audit concern overview by priority detail view - SAF Router Table (ROUT) field descriptions

Field	Explanation
Class name	The class name passed to the RACROUTE call.
Requestor name on RACROUTE	The requestor name passed to the RACROUTE call.
Subsystem name on RACROUTE	The subsystem name passed to the RACROUTE call.

Table 215. Audit concern overview by priority detail view - SAF Router Table (ROUT) field descriptions (continued)

Field	Explanation
Action (NONE or RACF)	The action to be taken for this requestor, class, and subsystem. 'NONE' indicates RACROUTE requests are to be ignored (RC=0), 'RACF' indicates RACF is to be called.

Table 216. Audit concern overview by priority detail view - Sensitive data sets (SENS)

Field	Explanation
Type of sensitive data set	The sensitivity type of the data set.
Data set name	The name of the data set.
Volume serial	The volume serial of the data set.
Access level that is exposure	The access level considered an exposure for this sensitivity type

Table 217. Audit concern overview by priority detail view - SMF subsystem (SMFO)

Field	Explanation
SMF subsystem name	The name of the subsystem for which the SMF options are set.
Summary of recording activity	A line describing what SMF records are suppressed and which are written

Note that the report type "SMF" can also refer to "System settings". See Table 205 on page 434.

Table 218. Audit concern overview by priority detail view - Subsystem (SSCT) field descriptions

Field	Explanation
Subsystem name	The subsystem name.
Subsystem type	The subsystem type (JES2, JES3, or blank)
Functional description	The name of the package normally creating this subsystem (if known to Security zSecure).

Table 219. Audit concern overview by priority detail view - Common storage (STOR) field descriptions

Field	Explanation
Storage area type	The virtual storage area type: (E/X)CSA or (E)SQA.
Storage area key	The storage protection key of the area.
Storage area subpool	The storage area subpool.
Start address	The start address of the storage area.
End address	The end address of the storage area
Length of storage area	The length of the storage area.

Table 220. Audit concern overview by priority detail view - Supervisor call (SVC) field descriptions

Field	Explanation
SVC number	The SVC number.
ESR number	For an extended SVC, the Extended Supervisor Router table index.
Current SVC requires APF	Whether the SVC requires the caller to be authorized.
Default function of the SVC	The function of the SVC; if shown in brackets, a guess based on the entry point name.
SVC residency	The virtual storage area where the SVC resides.
SVC entry point at	A description of the SVC's program name, module name and offset.

Table 221. Audit concern overview by priority detail view - Virtual storage (VSM) field descriptions

Field	Explanation
Storage area type	The virtual storage area type.
Start address	The start address of the storage area.
End address	The end address of the storage area.
Length of storage area	The length of the storage area.
% Area in use	For (E)CSA, the percentage used.

The system report types generally have the same structure: a summary by system, an overview display, and a detail display. The overview display is sorted by descending audit priority, listing the most important entries first. In an overview display, the important audit concerns are in the rightmost column.

STATUS AUDIT - MVS tables

The z/OS system report types available in zSecure Audit do not require a full CKFREEZE data set read. For each report type, the background is discussed, and sample displays or batch report output is presented and discussed.

These reports are available in batch mode, and under ISPF from the STATUS AUDIT MVS TABLES.

Note: In general, running the latest version of zSecure Collect APF-authorized results in the most detailed reports. Older versions and non-APF runs typically result in missing information.

The following system reports are available:

SYSTEM - MVS system settings report

The MVS system settings display shows an integrated display of MVS system parameters, system software levels, and settings. The amount of information available is increased if a later version of zSecure Collect is used or if zSecure Collect is run authorized.

This report is available on a live system; no CKFREEZE file is required.

For documentation on each of the fields displayed and the audit considerations involved, refer to the language reference for the NEWLIST TYPE=SYSTEM in Chapter 13, "SELECT/LIST Fields," on page 953. Furthermore, a second report SYSTEMAU shows the audit concerns. The audit concern report is part of the system settings report, but can also be run directly from CARLa scripts CKADSY80 (display), CKALSY80 (list, 80 characters wide) and CKALSY13 (list, 132 characters wide).

For more information on system audit concerns, see the description of AUDITCONCERN in AUDIT: System setting audit concerns "AUDITCONCERN" on page 961.

Figure 324 on page 442 shows the MVS system setting display.

Figure 325. MVS audit concerns summary display

The display contains the following fields of interest.

Table 222. System settings audit concerns - field descriptions

Field	Explanation
Pri	The highest priority for any audit concern for this system
Complex	The complex name
System	The system name
Count	The number of audit concerns for this system
Pri	The highest priority for the area
Area	The area of concern (HSM, MVS, SMF, SYSLOG or TSO)
Count	The number of audit concerns in the area

Select one of the areas to obtain a display of the audit concerns in it.

IPLPARM - IPL parameters report

The IPL parameters display shows the effective values of the IPL parameters (of the last IPL), the effective values of the LOADxx member that was used (with the volume serials for PARMLIB statements resolved), but first of all lists the operator-specified IPL parameters.

This report is available on a live system (no CKFREEZE file is required).

Documentation for each of the fields displayed, and the audit considerations involved, can be found in the language reference for SYSTEM NEWLIST in Chapter 13, “SELECT/LIST Fields,” on page 953. For detail information on the IPL parameters specified in IEASYSxx and the statements in LOADxx, refer to the sections in the Initialization and Tuning Reference on these parmlib members.

Figure 329. IPL parameters display (continued)

SMFSUBOP - SMF subsystem report

The SMF subsystem report checks whether the SMF record types most relevant for auditing are written, and generates an audit concern accordingly.

This report is available on a live system (no CKFREEZE file is required).

Background

SMF options can be set system-wide, and per subsystem. Each subsystem can be controlled separately. In addition, the pseudo-subsystems STC (for started tasks) and TSO (for interactive TSO users) can be specified. The default options for any subsystem not explicitly present are listed under the subsystem name *SYS*.

The system-wide options include the following:

- The action to take when SMF runs out of disk data sets or buffers: either lose records, halt the system or wait the system until space is available.
- The SMF recording data sets.
- Whether or not to write SMF record type 17 (scratch data set) for temporary data sets.
- The time-interval between the writing of subsequent SMF record types 23 (SMF Statistics).

These options are reported in the MVS system settings report (AU.S, MVS tables, SYSTEM). See also "SYSTEM - MVS system settings report" on page 441.

The options that can be set per subsystem include:

- The SMF records that are written to SMF.
- For each SMF record type, the subtypes that are written to SMF.
- The SMF exits that are active. (The exit IEFU83 for instance can be used to suppress SMF records independently of the recording activity settings.)

The information in the SMF subsystem report is based on in-storage SMF control blocks and is available both from the CKFREEZE file and from the current settings.

The SMF parameters are specified in parmlib member SMFPRMxx.

Auditing SMF subsystem settings

The following considerations apply when auditing SMF subsystems:

- Check the exits that are called for each subsystem.
- Check that SMF 7 is written. This record type indicates that SMF records were lost because the buffers or recording data sets were full, for example. If your system loses SMF records and does not write SMF 7, the loss of data is undetected.
- Check that the security related SMF records are written. For RACF: SMF 80 and 81, for Top Secret SMF 80 and for ACF2 is site definable (default is SMF 230). The RACF, ACF2 or Top Secret SMF records should not be suppressed. If you have RACF and MLACTIVE is set, or use other products that write SMF 83 records, SMF 83 should also be written.
- Check that either SMF 20 or SMF 30-1 is written. If neither is written, job starts are not logged. Note that RACF does not log all job starts.
- Check that SMF 14-15, 17-18, 60-62, and 64-67 are written. These records describe data set activity.
- If long-running jobs need to be accounted, check that interval recording is active.

The batch report to review the SMF subsystems is CKALSMFS. The interactive report is called CKADSMFS.

Figure 330 on page 448 shows a sample SMF subsystem overview display.

Figure 332. Batch SMF Subsystem Report

SUBSYS - Subsystem report

The subsystem report describes the MVS subsystems, their communications tables, and their function tables. The most common security exposures are recognized, and the subsystems receive a relative audit priority accordingly.

This report requires a `CKFREEZE` file. A non-authorized zSecure Collect run suffices.

Background

A subsystem is a program, or set of programs, that performs a set of functions, either on behalf of MVS, or whenever MVS requests the subsystems to perform a

specific function. An example (and required) subsystem is JES; other subsystems are NetView® and IMS. Subsystems are heavily used by third-party products as well as IBM products.

MVS communicates with the subsystems through the subsystem interface (SSI) Each subsystem has a subsystem control block (SSCT), which declares its presence and its name. In addition, each subsystem can have a communication vector table (SSVT), which contains a list of functions, indexed by number. MVS requests subsystem actions by this function number and depending on the function type, it goes to all subsystems (a *broadcast* function); to a specific subsystem; or to all subsystems in turn, until a subsystem handles the request. Each SSCT also has two 'user fields', SUSE and SUS2, which can be used to store numbers or pointers. Figure 333 shows an overview of the SSCT and SSVT subsystem structure.

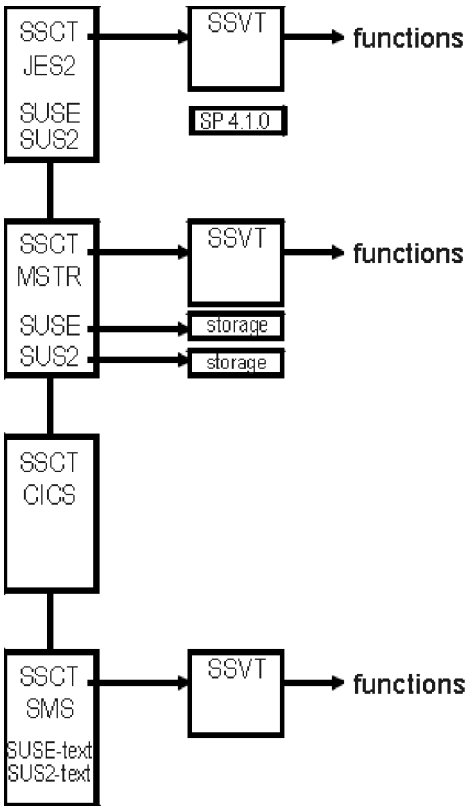

Figure 333. Subsystem Control Blocks

Subsystems are being used for the following purposes:

1. Intercepting MVS events like operator commands, WTO(R) messages, task termination, and address space termination. These are broadcasted to all subsystems (SSVT functions 4, 8, 9 ,10, and 50). Examples: JES, RACF.
2. Provide a system-wide calling interface to routines residing in common storage. The caller only specifies a function code. Example: SMS.
3. Provide a globally accessible storage anchor for subsystem control blocks. The SSCT contains two 'user' fields, SUSE and SUS2. The SSVT is not required for this purpose. An IMS subsystem is an example.

4. Provide a task (TCB) specific storage anchor for a subsystem. The Subsystem Affinity Table (SSAT) provides a fullword for each subsystem. No SUSE, SUS2, and SSVT pointers are required. This looks the same as a currently unused SSCT.

Auditing subsystems

The following considerations apply when auditing subsystems:

- Looking at the subsystem tables indicates which subsystem types a site has defined, and whether multiple versions are running at the same time.
- The order of the subsystems influences who gets control first for broadcast requests like operator commands and WTO(R).
- If a subsystem initialization has obtained its storage in a user storage key, programs from any address space can modify the control blocks of the subsystem. For instance, if the SSVT is in key 8, a broadcast function might be redirected causing the subsystem to remain uninformed or causing malicious code to get control. Similarly, the SSCT and areas pointed to by the user-pointers SUSE and SUS2 must not be writable.
- All information shown is available to unauthorized programs.

The batch report to review the subsystems is CKALSSCT. The interactive reports are called CKADSSC0 (concise) and CKADSSCT (detailed).

Note: The following displays first show the concise version of the subsystem report, and then describe the detailed report.

The concise subsystem overview display is shown in Figure 334.

Figure 336. Subsystem overview display

The overview panel contains the following fields of interest.

Table 228. Subsystem Communication Vector Tables - field descriptions

Field	Explanation
Complex	The name of the complex.
System	The name of the system.
Count	The number of subsystems defined.
Audit concerns	The number of subsystems with audit concerns.
Priority	The highest audit priority found.
Pri	The audit priority of the subsystem.
Name	The subsystem name.
Org	The position of the subsystem in the subsystem chain.
Type	JES subsystem type: JES2, JES3, or blank.
MFn	The maximum number of function entry points that can be defined. Each entry point can be used for several function codes.
FIB	Indicates whether serialization of Forward-In-Background (FIB) requests is required. E.g. TSO provides the FIB commands SUBMIT, CANCEL, and START.
PSS	Indicates whether the subsystem requires Primary Subsystem Support (PSS). If set, the subsystem is started under the primary JES. If not set, it is started under the master (MSTR) subsystem.
ARD	Indicates whether the subsystem supports the allocation of a special internal reader.
SUSE dat	The first eight characters from the SUSE contents.
SUS2 dat	The first eight characters from the SUS2 contents.
Description	Name of the package normally creating this subsystem.
Audit concern	Audit concerns identified.

Figure 337. Subsystem detail display

The detail display contains the following fields of interest.

Table 229. Subsystem Communication Vector Tables - additional field descriptions

Field	Explanation
SSCT	Location, residence, key, and subpool of the SSCT.
SSCTSUSE	Location, residence, key, subpool, and first 8 bytes of the SSCT SUSE user pointer.
SSCTSUS2	Location, residence, key, subpool, and first 8 bytes of the SSCT SUS2 user pointer.
SSCTSSVT	Location, residence, key, and subpool of the SSCT SSVT pointer.
Function	Function code supported by subsystem.
Address	Function entry point.
Where	Function residency.
Key SP	Key and subpool of the memory area where the function resides.
Program	Module name of the subsystem function.
Description	A description of the subsystem function.
InstrSc	Results from an instruction scan on the subsystem function.
Str	Results from a string scan on the subsystem function.
Length	Approximate length of the subsystem function.
AM	Addressing mode
Entry at	Module and offset information for the subsystem function.
Eye catchers	Storage display of the subsystem function.

VSM/WRITABLE - Memory reports

Security zSecure provides reports on the virtual memory layout of the system and the structure of the common storage. These report types can be generated for a live MVS system or using a CKFREEZE file.

This report is available on a live system. Consequently, no CKFREEZE file is required.

Background

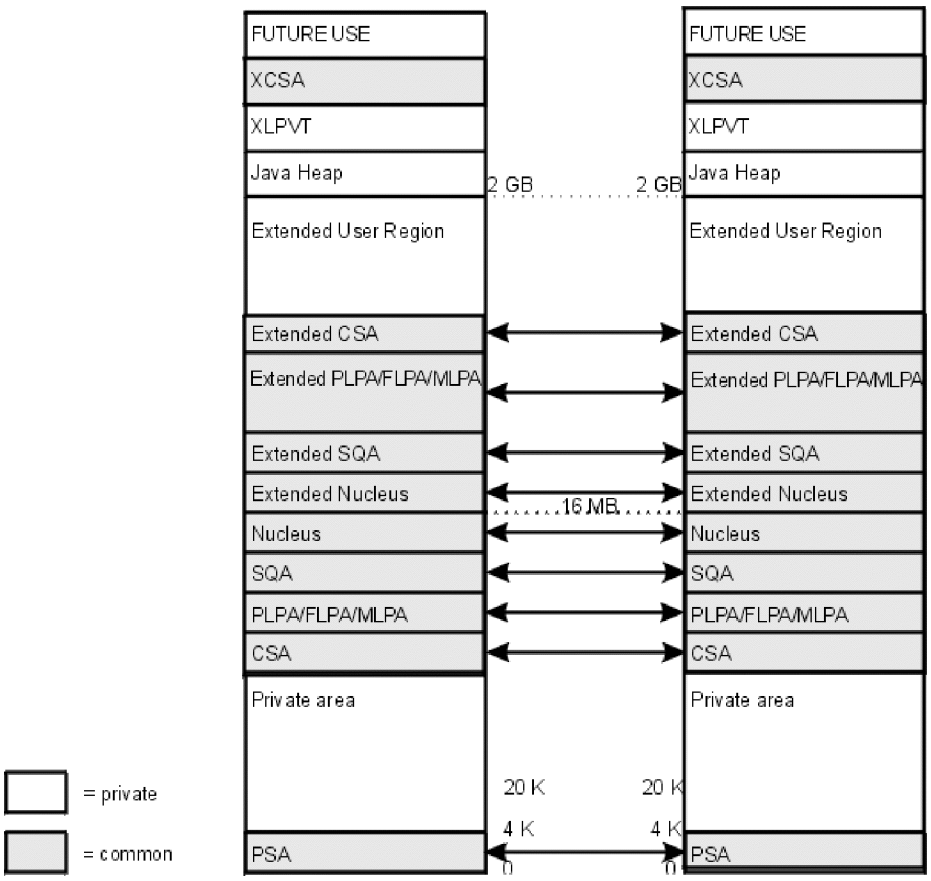

Figure 338. Virtual Memory Layout

Figure 338 shows the virtual memory layout of an MVS system. The location and size of each memory area is configuration-dependent. The shaded areas are *common* storage. Common storage areas are present and identical in every address user space. The non-shaded areas are *private*. Changes to private areas are local to one user. Changes to common storage are visible to and can affect every user and program on the system.

Security zSecure can report the storage areas location and size, which helps determine the residency of programs and tables known by address. In most Security zSecure reports, the memory areas are listed in the WHERE field. The data includes the percentage of CSA and ECSA used and the signals overflow into (E)SQA. The batch report for reviewing the system memory map is CKALSVSM. The interactive report is called CKADSVSM.

Auditing memory

Security zSecure can also report on the used memory areas in (E)CSA and (E)SQA. The report provides the location and size of each area as well as the storage protection key and subpool used. Shared memory areas with a storage protection key (*user key*) of 8 or higher might be a cause for concern. With this setting, any user might be able to change the memory which affects the operation of the program that uses the memory area. The sample reports to review common storage focus on these memory areas. If you want to report on not only the vulnerable, but all allocated common storage, you will need to edit the sample reports. The batch report to find writable common storage is CKALSCSM. The interactive report is CKADSCSM.

Sample ISPF displays are shown in the following figures. The batch reports are equivalent and are not included.

MPFMSG - MPF report

This report shows the message-specific data from the Message Processing Facility.

This report requires a CKFREEZE file. A non-authorized zSecure Collect run suffices.

Background

The MVS Message Processing Facility (MPF) allows the installation to alter the handling of system messages, which are normally displayed on operator consoles. Message handling is performed on the basis of the *message id*; in addition, a message handling default can be set, and is applied to all messages not handled explicitly. This default is shown as message id .NOENTRY.

MPF allows the message to be:

- Suppressed. If suppressed, it is not displayed on the operator consoles. It is included in the SYSLOG, unless the message has a routing code not included in SYSLOG.
- Automated. If automated, the message is made available to an automation subsystem, such as NetView.
- Sent to an exit. The exit is called each time the system issues the message, and is supposed to handle message processing. The exit can suppress the message.

The MPF parameters are specified in parmlib members MPFLSTxx. Several MPFLSTxx members can be active at the same time.

Auditing Message Processing

The following considerations apply when auditing MPF parameters:

- Check the messages that are suppressed. Sensitive messages, such as ICH408I on a RACF system, should not be suppressed if your installation has a security console.
- Check the exits used to process messages.
- Check the default handling of messages.
- Check the messages that are, and those that are not, automated.

The batch report to review MPF is CKALSMSG. The interactive report is called CKADSMSG.

Figure 342 on page 459 shows the MPF overview display.

Figure 342. Message Processing overview display

The display contains the following fields of interest:

Table 230. Message Processing Facility message intercepts - field descriptions

Field	Explanation
Complex	The complex name.
System	The system name.
Count	The number of message ids processed by MPF.
Suppress	The number of message ids suppressed by MPF.
Automate	The number of message ids automated by MPF.
ExitCall	The number of message ids for which an exit is called.
Audit concerns	The number of message ids for which audit concerns were identified.
Priority	The highest audit priority identified.
Pri	The current entry's audit priority.
Msg id	The message id of one message. All fields on the rest of the line apply to that message id.
Sup	Indicates whether the message is suppressed.
Auto	Indicates whether the message is automated; if it is, it contains the automation token.
Member	The parmlib member from which the MPF definition was taken.
Exit	The name of the exit called for the message.
Address	The address of the exit.
Where	Residency of the exit.
Exit at	Module information on the exit.
Audit concern	Audit concerns identified.

Figure 343 on page 460 shows the MPF detail display. It does not show additional information.

JOBCLASS - JES2 Job Class report

The JES2 job class report can be used to review the protection of the JES2 job classes for each system.

This report requires a CKFREEZE file made in an APF-authorized run of zSecure Collect.

Background

The JES2 job class definitions specify the attributes of each job class, such as default region size and time limits, command authorization, and SMF logging. The job class is usually selected through the CLASS= parameter in the JCL, but some sites assign a job class through an exit (IEFUJV, or JES2 exit 2 or 6).

The following security considerations apply to JES2 job class definitions:

- Users can issue MVS commands embedded in JCL. For each job class, an *authority level* determines the type of commands that can be issued, and a *command disposition* determines whether the command is ignored, must be verified by an operator, or is executed without verification. (The command authority level is determined through SAF, using resource names in the OPERCMDS class.)
- Bypass Label Processing (BLP) can be requested through the LABEL parameter of JCL DD command. If BLP is not allowed, all BLP requests are converted to NL (Non-Labelled).

  If BLP is allowed, users might be able to circumvent the protection of tape data sets. A job with BLP is allowed to ignore the actual data set name and volume serial on a tape JES2 leaves the JCL as it is, and leaves the authorization to a security product. DFP does a SAF request on the resource ICHBLP in the class FACILITY; READ access is required if the data set is opened for input, and UPDATE access is required for output.

  RACF can be used to control BLP. This requires both the TAPEVOL and FACILITY classes to be active; RACF checks the access of the user on the ICHBLP resource name in the FACILITY class.
- The writing of SMF record types 6 and 26 (JES2 output writer and Job Purge records) can be determined on a per-job-class basis. (If JES2 does attempt to

write these records, they can still be suppressed on a per-subsystem basis; see "SMFSUBOP - SMF subsystem report" on page 446.)

- The use of the JES2 exits IEFUJP (job purge exit) and IEFUSO (SYSOUT limit exit) can be determined on a per-job-class basis. If these exits are used in your installation, check that all active job classes use these exits.

Auditing Job Classes

The following considerations apply when auditing JES2 job classes:

- Check the command authorization and disposition. Check whether the OPERCMDS class is active, and check the profiles defined in the OPERCMDS class.class. Security zSecure warns you if the class is not active, or if the default return code of the class is too low.
- Check whether the job class allows BLP. If the job class allows BLP, check whether RACF is used to control it. Security zSecure warns you if the appropriate classes are not active, if no profile has been defined, or if the UACC on the profile used is READ or higher.
- If your installation requires SMF record types 6 and 26 to be written, check whether the job classes do not suppress these record types.
- Check whether the use of the IEFUJP and IEFUSO exits matches the requirements of your installation.
- Check whether the job class requirements for account numbers match the requirements of your installation.

The batch report to review the JES2 job classes is CKALSJCL. The interactive reports are called CKADSJC0 (concise) and CKADSJCL (detailed).

Note: The following figures show the detailed version of the job class report. The concise version of the report contains less information.

Sample ISPF overview and detail displays for the job class report are shown in the following figures.

Figure 344. Job class overview display

The overview display lists the job classes defined, sorted by audit priority. Job class O is considered a serious security problem, as indicated by an audit concern above 40.

Job class O is selected to show a detail display.

Audit concern
BLP RACF-protected, MVS Modify commands allowed, low RC on OPERCMDS, not
verified by operator
******************************* Bottom of Data ********************************
```

Figure 345. Job Class Detail Display

The audit concern for the job class makes the problem clear: MVS modify commands are allowed, not protected by RACF, and not verified by the operator. This allows any user to embed MVS commands in JCL, and then have them executed. BLP is allowed, but RACF-protected, so this is not a problem.

The displays contains the following fields of interest:

Table 231. Job Class Detail Display - field descriptions

Field	Explanation
Complex	The name of the complex examined.
System	The name of the system examined.
Subsys	The name of the JES2 subsystem.
Classes	The number of classes defined in the subsystem.
Audit concerns	The number of classes for which audit concerns were identified.
Priority	The highest audit priority identified.
Pri	Numerical audit priority.
C	The name of the job class.
Command	Indicates the command disposition, that is, the action taken by JES2 for MVS commands received. Can be any of the following: VERIFY (verify by operator) DISPLAY (display and execute) EXECUTE (execute but do not display) IGNORE (ignore silently)

Table 231. Job Class Detail Display - field descriptions (continued)

Field	Explanation
Auth commands	The command type authorized for the job class. Can be ALL (all command types) SYS (system commands) CONS (console commands) IO (input/output commands) and INFO (information commands)
BLP	Indicates whether Bypass Label Processing (BLP) is allowed.
HOLD	Indicates whether jobs are held before starting (these must be released by the operator). Some sites only allow BLP in combination with HOLD (as a security measure).
ACCT	Indicates whether account information is required.
Time	Indicates the default time limit.
Regio	Indicates the default region size.
SWA	Indicates SWA control block residency: above or below the 16 MB line virtual storage.
PL	Indicates the PROCLIB suffix
UJP	Indicates whether the IEFUJP job purge exit is taken.
USO	Indicates whether the IEFUSO SYSOUT limit exit is taken.
T6	Indicates whether SMF 6 records are written.
T26	Indicates whether SMF 26 records are written.
Audit concern	Audit concerns identified.

CONSOLE - Console report

The console report describes the system consoles for each system. Additional system-wide console parameters are displayed in the MVS settings report (“SYSTEM - MVS system settings report” on page 441).

This report requires a CKFREEZE file. A non-authorized zSecure Collect run is sufficient.

Background

MVS uses *operator consoles* as the principal means of communicating with the system. If all other I/O fails, MVS can still communicate through the hardware or system console. In addition to the system console, typically a number of MCS (Multiple Console Support) consoles are defined. MCS consoles are devices that are locally attached. In addition, consoles can be defined on devices accessed through z/OS Communications Server; these are called SMCS consoles. Also, software applications like TSO and SDSF can define *virtual* consoles called EMCS.(Extended MCS) consoles. There is also an older software method to create *subsystem consoles*, but their use is diminishing.

Each console can be limited with respect to the commands that can be entered on the console, through the AUTHORITY attribute. The least powerful authority is INFO. Increasingly powerful are CONS, IO, SYS and MASTER. If a console has MASTER authority, it can execute any MVS command. The only way to curb

MASTER authority is to use SAF controls - requiring LOGON for authentication and authorizing the actual command through the OPERCMDS class, based on the user identity, on the actual console being used or both.

The console parameters are specified in parmlib member CONSOLxx. For more information see the manual "MVS Operations: planning". For the current CONSOLxx member suffix, see “IPLPARM - IPL parameters report” on page 444.

Note that EMCS consoles are only shown on the report if a CKFREEZE data set is used that has been made with zSecure Collect 1.5.0 or higher running APF authorized.

Auditing Consoles

The following considerations apply when auditing consoles:

- Review the consoles defined, and the messages routed to each console. If a console has been defined for a specific purpose for example, as a security console, make sure the routing codes and message level have been set correctly.
- Check whether a logon is required for the consoles. This is a system-wide parameter that is set for all or none of the consoles. If any system console resides in a physically insecure area, the logon requirement should be set to REQUIRED. For a B1 system, the logon requirement should always be set to REQUIRED, except for the hardware console.
- Check the command authority for the consoles. The consoles that allow all command types to be issued should reside in a physically secure area. While Security zSecure cannot verify the location of any console, the device number can be used to track down the console.
- SMCS consoles without predefined LU are especially dangerous, since they can be accessed from anywhere. When login is optional and they fall under a catchall CONSOLE profile or the class is inactive, they can be accessed by anybody, and only class OPERCMDS safeguards which operator commands can be issued. When login is automatic, it also warrants inspection.
- For z/OS releases prior to z/OS 1.8, check whether an alternate console has been defined for essential consoles.

The batch report to review the consoles is CKALSCON. The interactive report is called CKADSCON.

Sample ISPF overview and detail displays for the console report are shown in the following figures.

```

Figure 346. Console Report

The display contains the following fields of interest:

Table 232. Console report - field descriptions

Field	Explanation
Complex	Name of the complex described
System	Name of the system described.
Consoles	Number of system consoles defined.
Audit concerns	Number of system consoles for which audit concerns were identified.
Priority	The highest audit priority found for any console.
Pri	The audit priority for the console.
Type	The type of the console; either MCS, EMCS, SubSystem, or blank if no console is connected.
Name	Name of the console.
Act	Whether the console is active or not. For subsystem consoles this is Yes when the console is dedicated to a subsystem, and No if it is in allocatable status.

Table 232. Console report - field descriptions (continued)

Field	Explanation
Con	The console number, counted per system. For EMCS consoles this field is empty.
Log	The system-wide logon requirement; can be OPT (optional), AUT (automatic), or REQ (required).
Userid	The `userid` logged on to the console.
Jobname	For in-use subsystem consoles, this is the subsystem to which the console is dedicated. For EMCS consoles this field contains the jobname that has the console activated.
LUname	The VTAM® Logical Unit name for SMCS consoles or terminal name for EMCS consoles.
Devn	The device number of the console.
Authority	The authority of the console. The master console has MASTER; the other consoles can have ALL (almost equal to master), or one or more from SYS (system commands), IO (I/O commands), CONS (console commands), and INFO (display commands).
CmdSys	System that receives the commands typed on the console. "*" means the system where the console is defined.
Profile	The name of the profile that protects the console.
Routecode	The routing codes of the console.
Level	The message level of the console. See “LEVEL” on page 1007 for a list of values.
Mon	Monitored events like JOBNAMES, SESSION, and STATUS.
HC	For EMCS consoles, this field indicates whether the console receives hardcopy-only messages.
Aut	For EMCS consoles, this field indicates whether the console receives messages that were automated by MPF.
UD	Indicates whether the console receives undirected messages.
Int	Receive messages for internal ids (console 0).
Unk	Receive messages for unknown console ids.
DOM	Whether this console receives Delete Operator Messages (DOM) and from where. It's values can be ALL (all systems in sysplex), NORMAL (this system), and NONE (no system).
Alternat	The name of the alternate console.
Jobid	For EMCS consoles this field contains the job id of the job that has the console activated.
PfkTab	The name of the function-key table used.
Switchto	The name of a console to which this console has been switched. Normally, this is empty.
Mig	Migration id of an EMCS console.
CNID	The CoNsole ID. Used to route commands, responses and messages.
Key	The key that is assigned by the OPERPARM data to an EMCS console.
Audit concerns	Audit concerns identified.

The console detail display is shown in Figure 347 on page 467.

Figure 347. Console detail display.

The detail display does not contain any additional fields.

PPT - Program Property Table report

The Program Property Table report describes the MVS PPT, which defines special attributes for selected authorized programs.

The report requires a CKFREEZE file made in an APF-authorized run of zSecure Collect.

Background

The Program Property Table (PPT) is an MVS table that describes APF-authorized programs. It contains attributes that are assigned to these programs as they are loaded from an APF library as a job step program. These attributes can be taken from the default load module IEFSDPPT or from parmlib member SCHEDxx. For a

number of address spaces default PPT definitions are shipped with the operation system, and sometimes sites modify these.

The attributes that can be set in the PPT include the following:

- Bypass SAF. If the BYPASS flag is set, data set accesses by the program are not subject to SAF security checks.
- The key in which the job step runs. Keys in the range 0 to 7 imply authorization.
- Data set integrity. If the NODSI flag is set, data sets used by the program can be deleted by another program while still being used.

Auditing the Program Property Table

The following considerations apply when auditing the Program Property Table:

- A task that bypasses password and SAF protection is very dangerous if it can be called by arbitrary users and be induced to read from or write to user-specified data sets. So programs like HASJES20 and DFHSIP should never have bypass password authority, especially if there is no program protection in place. On RACF systems, you can use the Authorized Programs report in "APFPROT - Authorized Programs reports" on page 328 to check on the protection of PPT-authorized modules.
- Tasks with system key should be audited like AC(1) modules: they are authorized to bypass system security, and if you do not know anything about them you had better protect them from execution by arbitrary users.
- Tasks without data set integrity that depend on data sets can be brought down by accident (e.g. deleting/renaming a PROCLIB in JES2 can be done if HASJES20 has NODSI, but the next job conversion for the DDname causes JES2 to abend). So NODSI usually creates an availability risk.

The batch report to review the sensitive data sets is CKALSPPT. The interactive report is called CKADSPPT.

Sample ISPF overview and detail displays for the PPT report are shown in the following figures.

```

Figure 348. Program Property Table overview display

The overview display contains the following fields of interest:

Table 233. Program Property Table overview - field descriptions

Field	Explanation
Complex	The name of the complex examined
System	The name of the system examined
Count	The number of PPT entries
Audit concerns	The number of PPT entries for which audit concerns were identified.
Priority	The highest audit priority found for any PPT entry.
Pri	The audit priority for the PPT entry.
Program	Name of the program.
Key	The PSW key in which the program runs. A key in the range 0 to 7 indicates authorization.
Bypass	Indicates whether the program bypasses SAF.
NoDSI	Indicates whether the program uses data set integrity (blanks) or not (NoDSI).
Modif	Indicates whether the entry has been modified (Modif) after the original initialization from the IEFSDPPT module (which supplies the defaults). If it was added to the table, it is considered modified too.
NonSwap	Indicates whether the program is marked non-swappable.
NonCan	Indicates whether the program can be cancelled (blank) or not (NonCan).
Priv	Indicates whether the program is privileged. A privileged program is not swapped unless in a long wait state.
Systask	Indicates whether the program is a system task (Systask) or not (blanks). A system task is not timed.
Audit concern	Audit concerns identified.

Note that some audit concerns might be suffixed with *(IBM default)*, which indicates that the program property is in the IBM supplied IEFSDPPT for the OS level being investigated. This indication is separate from the **Modif** indicator that indicates whether the entry was ever modified from or added to the default PPT. For example, the preceding settings for ERBMFMFC and ERB3GMFC (for example, RMF™) are the defaults on the OS level being examined, yet **Modif** shows that the entry was modified, due to an explicit specification in a SCHED*xx* member in parmlib.

The PPT detail display is shown in Figure 349 on page 470.

SVC - Supervisor Call report

The SVC report displays the Supervisor Calls and Extended Supervisor Routers (ESRs).

This report is available on a live system. Consequently, no CKFREEZE file is required.

Background

A SuperVisor Call (SVC) is an instruction that can be used by authorized and unauthorized programs to call a system function. The system contains an SVC*table* with information on all SVCs defined. The SVC instruction contains an SVC*number* that determines the SVC table entry to be used. The entry defines how control is to be transferred by the SVC instruction; that is, to which address and under which locks control is transferred. An SVC routine always receives control in Supervisor state, key 0.

An SVC table entry can contain the APF bit. If it is on, APF authorization is required to execute the SVC.

An SVC entry can be marked with the ESR bit. In this case, the address in the routine identifies a second-level SVC table called the ESR table. The system uses the contents of register 15 (called the *ESR number*) to identify the SVC table entry in this secondary table.

SVC routines must be in common storage to be callable from all address spaces.

The SVC table can be updated using the SVCUPDTE service. The SVCUPDTE service keeps track of the last update to the SVC in the SVC update table. Security zSecure reports on updates both with and without SVCUPDTE.

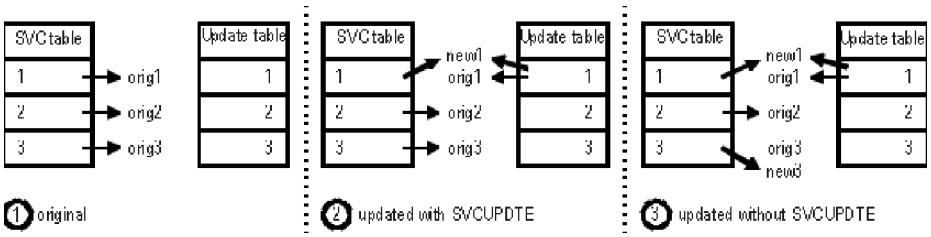

Figure 350. SVC updates

Auditing supervisor calls

The Supervisor Call routine is executed with the highest system authority, and can be called by any program if the APF bit in the SVC table is off. Because of this authority, SVC routines should take care not to introduce security leaks into the system by allowing a user more latitude than he should have according to the site security policy.

Regretfully, SVC routines exist that were built without adhering to the IBM guidelines or consulting a security expert. Most important features of such SVCs are that they can easily crash the system and that they can be used by system experts to circumvent all access control measures implemented in the operating system software.

On average, IBM SVCs tend to be safer than third-party vendor and site-designed SVC routines. Because of this, non-standard or front-ended SVC routines receive a higher audit priority than standard SVCs.

The batch sample to review the SVCs is CKALSVC, which produces three reports (two overview and one detailed report). The interactive reports are called CKADSVC0 (concise) and CKADSVC (detailed).

Note: The following information shows the concise version of the SVC report and then provides a description of the detailed report.

The concise SVC overview display is shown in Figure 351.

Figure 354. SVC Call Audit detail display

The detail display contains the following fields of interest:

Table 236. SVC Call Audit detail display - field descriptions

Field	Explanation
Idx	An index indicating the *versions* of the SVC grouped on one line. The index can be any of the following: C is current N result of last update O the version prior to the last update I the expected routine based on the module name The fields on the rest of the line all describe the same version of the SVC.
Where	SVC routine residency.
Key	SVC routine storage area key.
SP	SVC routine storage area sub-pool.
Program	SVC routine module name.
InstrSc	Results of an instruction scan.
Eye catchers	In storage eye catchers.
Address	SVC routine address.
Length	Approximate length of the SVC routine.
Entry at	Module and offset information.
SVC same as	Lowest SVC and optionally ESR number with the same address.
Result	Result of SVC code disassembly.
Appl	Application the SVC belongs to.
Result	Result of disassembly of current SVC.

Table 236. SVC Call Audit detail display - field descriptions (continued)

Field	Explanation
SVCUPDTE	Number of updates made using SVCUPDTE.
Sf	PARMLIB member IEASVCxx suffix used in SVCUPDTE call.
Last update	Date of last SVCUPDTE call.
Caller	Address of last caller of SVCUPDTE.
Where	Last SVCUPDTE caller's residency.
Module	Last SVCUPDTE caller's module information.
Index	An index indicating the version of the SVC for which the type is shown on the line, one of Current (from SVC table). Old (from SVCUPDTE table), Expected (from documentation).
Typ	SVC type. This can be 1, 2, 3/4, or 6. The SVC type determines the load module naming convention.
APF	Indicates whether APF-authorization is required to call the SVC.
ESR	Indicates whether the SVC is an ESR.
Att	SVC attributes. N for non-preemptive, S for assisted, and A for AR mode.
Locks	SVC locks. C for CMS lock, D for DISP lock, L for LOCAL lock, O for OPT lock, and S for SALLOC lock.
Instr/Str/SVC	Results of instruction, String, and SVC scans.
Audit concern	Audit concerns identified.
First 256 bytes of SVC	The start of the SVC is shown both in hex and text. Nonprintables have been replaced with periods in the latter.

PC - Program Call report

The Program Call report displays the Program Call routines, their entry tables, and the connected address spaces.

The report requires a CKFREEZE file made in an APF-authorized run of zSecure Collect.

Background

The Program Call (PC) is a more modern alternative to the SVC (Supervisor Call). (In fact, IBM urges vendors to use PC instead of SVC because it is more efficient.) Program Calls are instructions for calling a routine outside the current program. The routine can be executed in another address space and with different authorization.

The Program Call instruction accepts a PC *number* that determines the routine to be called. The first part of the number is the *Linkage Index* LX that determines the address of an *Entry Table* ET . The second part is the *Entry Table Index* EX that identifies an entry in the entry table.

The entry defines the address, the address space, and the authorities used when control is to be transferred by the PC instruction.

An entry table can be shared between address spaces. MVS tries to keep the linkage index the same for all address spaces sharing an entry table, but this is not a hardware requirement. If an entry table is to be shared between all address

spaces, MVS allows allocation of a *system* LX to this entry table. A non-system LX/entry table can only be used from address spaces explicitly *connected* to the entry table.

The Entry Table entry can define the following features:

1. The address space where to execute the PC routine (may be the current address space).
2. Supervisor mode or Problem program mode.
3. The Program Status Word (PSW) protection key that the Program Call runs in. This key determines the memory that may be accessed by the PC routine. A key in the range 0 to 7 makes the PC routine authorized.
4. The set of PSW keys the routine may switch to (the EKM or Entry Key Mask). One or more keys in the range 0 to 7 make the PC routine authorized.
5. Whether the EKM is replacing or expanding the current authority.
6. The set of PSW keys that authorize use of this entry (the AKM or Authorized Key Mask).
7. The address of the LPA Latent Parameter Area . In MVS this is a 16 byte area that contains linkage stack origins and 2 user fullwords.

Many MVS functions have been coded to be independent of the actual PC number assigned. This is accomplished by loading the actual PC number from a certain offset in the System Function Table or SFT.

Each Program Call can have a *Latent Parameter Area* (LPA, not to be confused with the link pack area). This is an area at a location fixed when the PC was created. In this area, there are two 4-byte fields available for use by the PC routine. Most PCs do not use these fields, or use them to store simple values. However, some PCs use these fields to store one or two pointers to larger parameter areas. The Latent Parameter Area is shown in Figure 355.

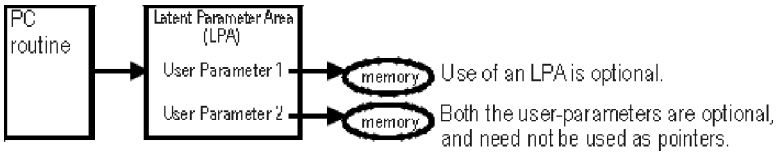

Figure 355. PC Latent Parameter Area

Security zSecure tries to trace the LPA pointers, to see if they point to common storage. If any of these pointers appears to point to *writable* common storage, Security zSecure warns you because there is a chance that any user can overwrite parameters or storage used by the Program Call.

Theoretically, an entry table can have different linkage indices in different address spaces; as a result, the same PC routine, with the same parameters, would have several different PC numbers. This is illustrated in Figure 356 on page 477.

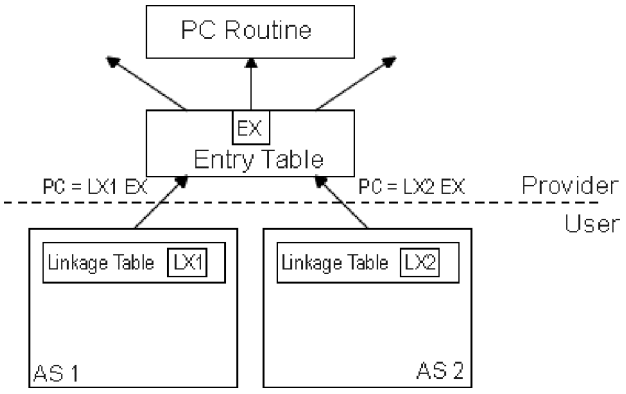

Figure 356. Program Call with more than one LX

However, MVS tries to prevent this situation from occurring. Security zSecure is able to report these cases correctly. (No audit concern is generated.)

Auditing Program Calls

Compared with Supervisor Calls (SVCs), the PC allows more precise control over authorities required and obtained. However, the same kind of audit concerns apply as for SVCs.

The PC routines requiring most audit attention are the routines that:

- Can be executed from any address space (that is, routines that reside in a system Entry Table).
- Can be called by unauthorized programs (the AKM contains key 8).
- Run authorized (that is, routines that run in supervisor state, add a system key to the EKM, or have a system key as EK).
- Reside in globally readable common storage or libraries (allowing uncontrolled disassembly).
- Reside in private storage (PVT or EPVT), but are not space-switching. Each caller can execute a different version of the Program Call.

  If the Program Call executes authorized and the caller can be unauthorized, a Program Call in the (E)PVT might allow any user to gain authorization.
- Have an LPA with user-pointers pointing to writable common storage.

The batch sample to review the Program Calls is CKALSPC, which produces six batch reports, including overview and detailed reports. The interactive reports are called CKADSPC0 (concise) and CKADSPC (detailed).

Note: The following information first shows the concise version of the Program Call report, and then describes the detailed report.

The concise ISPF Program Call report is split into four levels. The first level shows the number of system-wide and non-system-wide program calls per system analyzed, and the highest audit priority identified, as shown in Figure 357 on page 478.

Figure 358. Program Call second-level display (concise)

The second-level display summarizes the system-wide Entry Tables (ETs). For each entry table, it shows the owning address space, the number of ET connections (blank for a system-wide ET), and the number of Program Calls defined in the entry table.

Select any row for an overview of the Program Calls defined in the ET.

```

Figure 359. Program Call overview display (concise)

The Program Call overview display shows the PCs defined in a single Entry Table, sorted by audit priority. It can be scrolled left and right to view additional information. The display contains the following fields of interest:

Table 238. Program Call Audit - field descriptions

Field	Explanation
Pr	The audit priority.
PCnum	The Program Call number of the PC routine.
Aut	Indicates whether the caller of the PC routine must be authorized.
Caller	The job name of the address space connected to the PC (blank: available system-wide, or no connections). The value <more>indicates several callers were identified; these are all listed on the detail panel.
Runs in	The job name of the address space in which the PC runs, if it is a space-switching PC. This field is blank for non-space-switching PCs, as these execute in the caller's address space.
Description	Description of the PC, based on the index in the SFT, or a guess based on the module name. In the latter case, the description is surrounded by parentheses.
Where	The residency of the Program Call routine.
Entry at	Module information and offset.
Audit concern	Audit concerns identified.

Select any PC entry on the overview panel for a detailed view. The detailed view does not add additional fields; for a non-system-wide PC, all callers are listed. The

detail display is shown in Figure 360.

Figure 360. Program Call detail display (concise)

The next set of displays shows the detailed Program Call report. You are advised to skip these displays, and use concise reporting, until you are familiar with Program Calls in general and the PCs on your system in particular. For clarity, the same system and PC routines are examined as in the concise displays above.

The Program Call first-level display is shown in Figure 361.

```

Figure 362. Program Call overview display

The overview display can be scrolled right repeatedly to show more information; these fields are repeated on the detail display of any one Program Call. The overview display contains the following fields of interest:

Table 239. Program Call Audit display - field descriptions

Field	Explanation
Pr	The audit priority.
PC num	The Program Call number of the PC routine.
A	Indicates whether the caller of the PC routine must be authorized (Y) or not (N).
Caller	The job name of the address space connected to the PC (blank: available system-wide, or no connections). The value '<more>' indicates several callers were identified; these are all listed on the detail panel.
AKM	The authorized key mask, a bit field indicating the PSW keys that a caller can have.
Runs in	The job name of the address space in which the PC runs, if it is a space-switching PC.
M	The mode in which the PC runs: supervisor state (S) or problem-program mode (P).
K	Indicates the PSW key that the PC runs in. Keys in the range 0 to 7 imply authorization.
oEKM	Five character field where the first character indicates how the PC runs with the caller's key: • Mask OR-ed with the Entry Key Mask EKM (O). • EKM replaces the caller's key mask (R) The remaining four characters indicate the EKM used.

Table 239. Program Call Audit display - field descriptions (continued)

Field	Explanation
T	The type of the PC: basic (B) or space-switching (S).
Where	The residency of the Program Call routine.
Program	The module name of the Program Call routine.
Eye catchers	Visible eye catchers from the Program Call routine.
Address	Program Call routine entry point.
Where	Program Call routine residency.
Entry at	Module information and offset.
Length	Approximate length of the Program Call code.
AM	Addressing mode.
InstrSc	Instruction scan hits.
Str	String scan hits.
LPArea	Residency of the Latent Parameter Area (LPA).
K	Storage protection key of the LPA memory area, LPA param1/param2 area.
SP	Sub-pool of the LPA memory area, LPA param1/param2 area.
Px area	Residency of the LPA param1/param2 area.
SFT	Index of the PC code in the System Function Table (SFT).
Description	Description of the PC, based on the index in the SFT, or a guess based on the module name. In the latter case, the description is surrounded by parentheses.
Audit concern	Audit concerns identified.

On the overview display, select any line for a detailed display of the Program Call.

Figure 363. Program Call Detail Display

The detail display contains the following fields of interest:

Table 240. Program Call Audit display - field descriptions

Field	Explanation
PC num	All Program Call numbers by which the PC routine can be called.
LX-seqno	The sequence number for a reused Linkage Index. To be used to verify whether a PC instruction was intended for the current incarnation of the LX.
Caller	The job names of all connected address spaces.
ASID	Address space ID of all connected address spaces.
Dorm	Indicates whether the LX connect is dormant or not.
LX	The Linkage Index of the Entry Table of the Program Call.
Syst	Indicates whether the Linkage Index is a system index.
LX-owner	The job name of the Linkage Index owning address space.
ASID	The Address Space ID of the Linkage Index owner.
SFT	The index in the System Function Table.
Description	Description of the PC, based on the index in the SFT, or a guess based on the module name. In the latter case, the description is surrounded by parentheses.
PSW Mode	Indicates the state in which the PC runs (Supervisor or Problem-program mode).
Key	The PSW key in which the PC routine executes.
Type	The type of PC routine (Stacking or Basic).
EX	The index of the PC in the Entry table.
Syst	Indicates whether the Entry Table is a system entry table.

Table 240. Program Call Audit display - field descriptions (continued)

Field	Explanation
ET-owner	The job name of the Entry Table owning address space.
ASID	The Address Space id of the Entry Table owner.
Connects	The number of address spaces connected to the Entry Table (blank for a system ET).
Authorized Key Mask	A list of the PSW keys that a caller can have.
Entry Key Mask	A list of the keys in the Entry Key Mask EKM.
usage	Indicates whether the EKM is OR-ed with the caller's key mask, or REPLACEs it.
Storage area	Which storage area is described on this line (PC routine, latent parameter area, or LPA param1/param2).
Address	The address of the PC routine, latent parameter area, and LPA param1/param2.
Where	The residency of the PC routine, latent parameter area, and LPA param1/param2.
Key	The storage area key of the PC routine, latent parameter area, and LPA param1/param2.
SP	The storage area subpool of the PC routine, latent parameter area, and LPA param1/param2.
Length	Approximate length of the PC routine.
AM	Addressing mode.
Module	Module name of the PC routine.
Instr/Str/SVC Scan	Results of instruction, string, and SVC scans.
Audit concern	Audit concerns identified.
First 256 bytes of PC routine	The start of the PC routine is shown both in hex and text. In the text, values that cannot be printed have been replaced with periods.

TAPE - Tape protection settings

The TAPE report shows the effective tape settings. It also shows CA-1 specific settings.

The report requires a CKFREEZE file made in an APF-authorized run of zSecure Collect.

Documentation for each of the fields displayed can be found in the language reference for the SYSTEM NEWLIST in Chapter 13, “SELECT/LIST Fields,” on page 953.

Figure 364 on page 485 shows a sample Tape protection settings display.

Figure 364. Tape protection settings display

IOAPP - I/O Appendage report

The I/O appendage report describes the authorized I/O appendages table.

This report is available on a live system (no CKFREEZE file is required).

Background

I/O appendages are exit routines that receive control during certain stages of an I/O operation. They are entered in supervisor state.

Appendages are identified by a two-character identifier, that is passed to OPEN as part of the Data Control Block (DCB) describing the file to be opened.

OPEN tries to locate a module named IGG019nn where *nn* is the appendage id. Just naming the module this way is not enough, it looks for a module that:

1. Resides in an authorized library (the Authorization Code of the module is not checked, hence AC=0 is sufficient and desirable).
2. Has the RENT attribute - it must be reenterable.

If these conditions are not met, the operation is stopped using abnormal end code 806.

An appendage that is part of the authorized appendage table can be requested by an unauthorized user, and runs in supervisor state. Hence, the appendage can bypass access controls, and should contain extensive authorization checking code if it is used to do exactly that.

In the past, End-of-extent appendages that reset the extents from the actual data set boundaries to the complete volume have been a popular way for DASD management packages to obtain access to the complete volume. Such an appendage is a security exposure if it is added to the authorized I/O appendage table, since it bypasses data set access control.

The I/O appendage parameters are specified in parmlib member IEAAPP00.

Auditing I/O appendages

The following considerations apply when auditing I/O appendages:

- All appendages in the table should be reviewed to check that they are indeed properly designed for use by unauthorized programs.
- Prior to DFSMS 1.4, there is one entry automatically added by MVS, which is E4 (channel end/abnormal end appendage for interactive terminal facility, or IGG019E4). Verify that IGG019E4 appendage present in the system is valid and has not been replaced by an invalid, potentially malicious version.

The batch report to review the I/O appendages is CKALSIOA. The interactive report is called CKADSIOA.

For more information on any I/O appendage resident in-storage, see the exit report.

Sample ISPF overview and detail displays for the I/O appendage report are shown in the following figures.

Figure 367. Batch I/O Appendage report

The reports contain the following fields of interest:

Table 241. Batch I/O Appendage report - field descriptions

Field	Explanation
Complex	The name of the complex examined.
System	The name of the system examined.
Appendages	The number of I/O appendages.
Audit concerns	The number of I/O appendages for which audit concerns were identified.
Priority	The highest audit priority for any of the I/O appendages.
Pri	Audit priority. A higher number indicates greater concern.

Table 241. Batch I/O Appendage report - field descriptions (continued)

Field	Explanation
Id	The I/O appendage ID. When combined with the fixed prefix IGG019, this makes up the appendage load module name.
Type	The I/O event types for which the appendage can be used.
Audit concern	Audit concerns identified.
Description	Description of the I/O appendage.
Entry point	Address of the default I/O appendage routine (if the I/O appendage resides in-storage).
Residency	The virtual storage area where the appendage resides.
Eye catchers	The start of the I/O appendage, usually containing eye catchers.
Conforms to default	Indicates whether the appendage conforms to the default defined.

IPSTACK - Communications Server IP stack display report

The Communications Server IP stack display report lists the TCP/IP stack configuration settings.

The data for this report is only available if a `CKFREEZE` file has been created during an APF-authorized run of zSecure Collect (CKFCOLL) with option `TCPIP=YES`. For details on creating this file, see Chapter 16, "zSecure Collect for z/OS," on page 1591.

Detailed field information is available by pressing F1 on an IP report selection panel or on any field within a panel. Descriptions are also provided in the SELECT/LIST fields chapter. For the IP configuration data field names and descriptions for IP* NEWLIST types, see "IP: Profile information for TCP/IP configuration" on page 1054. For information on the IP configuration data fields used for SMF event reporting (SMF record 119, subtype 4), see "SMF: SMF records" on page 1276.

The batch report to review the IP stack is CKALSIP. The interactive report is called CKADSIP.

Sample overview and detail display panels for the Communications Server IP stack display report are shown in Figure 368 and Figure 369 on page 489.

Audit concern
No access control to/from foreign and local networks
 ******************************* Bottom of Data ********************************
```

Figure 369. IP Stack detail display

Auditing the IP stack

The following considerations apply when auditing the IP stack.

- Ports below 1024 should be reserved, so users and programs cannot bind to low TCP and UDP ports by default and masquerade as legitimate services.
- IPv4 and IPv6 IP filtering support and IPSec tunnel support should be active.
- The audit trail should show attacks stopped by filter rules, including default filter rules.
- The audit trail should show all SMF119, FTPCLIENT, IFSTAT, IPSECURITY, PORTSTAT, TCPINIT, TCPIPSTACK, TCPIPSTAT, TCPTERM, TN3270CLIENT, and UDPTERM records.
- There should be access control to and from foreign and local networks.
- Access control should be required to and from foreign networks.
- There should be access control within the local network.
- Even when IPSTACK shows no concern of users being able to modify TCP/IP security parameters, it is possible that certain users are able to do so. To show the access of individual users to sensitive resources, examine the following reports:
  - "TRUSTUSR - Trusted users report" on page 292
  - "SENSTRUS - Sensitive Data Trustees report" on page 317
- Denial-of-service attacks should be attributable to authenticated users.
- By default, no user should be able to read netstat ALL, ALLCONN, ARP, BYTEINFO, CACHINFO, CLIENTS, CONFIG, CONN, DEFADDRT, DEVLINKS, GATE, HOME, IDS, ND, PORTLIST, RESCACHE, ROUTE, SLAP, SOCKETS, SRCIP, STATS, TELNET, TTLS, UP, VCRT, VDPT, VIPADCFG, and VIPADYN output. Being able to read sensitive netstat data could facilitate mounting an attack.
- By default, no user should be able to control the TCP/IP security parameters in effect after the next stack setup modification.

  Even when IPSTACK shows no concern of users being able to control the TCP/IP security parameters in effect after the next stack setup modification, it is possible that certain users are able to do so. To show the access of individual users to sensitive resources, examine the TRUSTUSR - Trusted users report or the SENSTRUS - Sensitive Data Trustees report.

IPPORT - Communications Server IP ports display report

The Communications Server IP ports report describes the port configuration of TCP/IP stacks. The data for this report is only available if a `CKFREEZE` file has been created during an APF-authorized run of zSecure Collect with option `TCPIP=YES`. For details on creating this file, see Chapter 16, "zSecure Collect for z/OS," on page 1591.

For detailed field information, press F1 on the selection panel or any field to open the help. You can also review the field descriptions in "IP_PORT: TCP/IP port configuration" on page 1061.

The batch report to review the IP ports is CKALSIP. The interactive report is called CKADSIP.

Sample ISPF overview and detail displays for the Communications Server IP ports report are shown in Figure 370 on page 491 and Figure 371 on page 491.

Figure 371. IP ports detail display

Auditing the IP ports

The following considerations apply when auditing the IP ports.

- SAF parameters should prevent users and programs from binding to privileged ports. Being able to bind to a privileged port allows a user to masquerade as a legitimate service. For some ports it also allows one to receive passwords.

  Even when IPPORT shows no concern of users being able to bind to privileged ports, it is possible that certain users are able to do so. To show the access of individual users to sensitive resources, examine the following reports:

  – "TRUSTUSR - Trusted users report" on page 292
  – "SENSTRUS - Sensitive Data Trustees report" on page 317

IPRULE - Communications Server IP rules display report

The Communications Server IP rules display report describes the IP filter rule configuration of TCP/IP stacks. The field values reported can be changed through the use of IPSEC statements.

The data for this report is only available if a CKFREEZE file has been created during an APF-authorized run of zSecure Collect with option TCPIP=YES. For details on creating this file, see Chapter 16, "zSecure Collect for z/OS," on page 1591.

For detailed field information, press F1 on the selection panel or any field to open the help. You can also review the field descriptions in "IP_RULE: TCP/IP Rule Configuration" on page 1073.

The batch report to review the IP rules is CKALSIP. The interactive report is called CKADSIP.

Sample ISPF overview and detail displays for the Communications Server IP rules display report are shown in Figure 372 and Figure 373.

IPROUTE - Communications Server IP routes report

The Communications Server IP routes report describes the route configuration of TCP/IP stacks.

The data for this report is only available if a CKFREEZE file has been created during an APF-authorized run of zSecure Collect with option TCPIP=YES. For details on creating this file, see Chapter 16, "zSecure Collect for z/OS," on page 1591.

For detailed field information, press F1 on the selection panel or any field to open the help. You can also review the field descriptions in "IP_ROUTE: TCP/IP route configuration" on page 1072.

The batch report to review the IP route configuration is CKALSIP. The interactive report is called CKADSIP.

Sample ISPF overview and detail displays for the Communications Server IP routes report are shown in Figure 378 on page 495 and Figure 379 on page 495.

IPRESOLV - Communications Server resolver report

The Communications Server IP resolver report describes the Communications Server (CS) Resolver configuration settings.

The data for this report is only available if a CKFREEZE file has been created during an APF-authorized run of zSecure Collect with option TCPIP=YES.

For details on creating this file, see Chapter 16, "zSecure Collect for z/OS," on page 1591. For detailed field information, press PF1 on the selection panel or on any field to open the help. You can also review the field descriptions in "IP_RESOLVER: CS Resolver configuration" on page 1066.

The batch report to review the IP resolver configuration is CKALSIP. The interactive report is called CKADSIP.

Figure 384 on page 498 shows a sample ISPF detail display for the Communications Server IP resolver report.

****************************** Bottom of Data ********************************
```

Figure 384. Communications Server IP resolver display

Auditing the IP resolver

The following considerations apply when auditing the IP resolver.

- By default, no user should be able to redirect all DNS queries from their address spaces.
- By default, no user should be able to control CS Resolver configuration parameters. Being able to do so enables a user to redirect all IP traffic to host names from all users address spaces after the next CS Resolver setup modification.

  Even when IPRESOLV shows no concern of users being able to control CS Resolver parameters, it is possible that certain users are able to do so. To show the access of individual users to sensitive resources, examine the following reports:

  – "TRUSTUSR - Trusted users report" on page 292
  – "SENSTRUS - Sensitive Data Trustees report" on page 317

STATUS AUDIT - MVS extended tables

This section describes the z/OS system report types available in Security zSecure that require a full CKFREEZE data set read. For each report type, the background is discussed, and sample displays or batch report output are presented and discussed.

The report types described in this section are available in batch mode, and under ISPF in STATUS AUDIT category MVS extended.

Note: In general, running the latest version of zSecure Collect APF-authorized results in the most detailed reports. Running older versions of zSecure Collect as non-APF typically creates reports with missing information.

The following system reports are available:

- DMS - DMS setting report
- EXITS - Exit and table report
- DASDVOL - DASD volume report
- MOUNT - Effective UNIX mount points
- SENSITIVE - Sensitive Data Set report

DMS - DMS setting report

The DMS report describes the system's SAMS:Disk or DMS (Disk Management System) settings. A full CKFREEZE file read is required.

This report requires a CKFREEZE file. A non-authorized zSecure Collect run suffices.

The batch report to review DMS settings is CKALSDMS. The interactive report is called CKADSDMS. The language reference section for this report type is (TYPE=SYSTEM) included in Chapter 13, “SELECT/LIST Fields,” on page 953.

A sample display is included in Figure 385.

```

****************************** Bottom of Data ********************************
```

Figure 385. DMS Settings display

The display contains the following fields of interest:

Table 242. DMS system settings - field descriptions

Field	Explanation
DMS PARMLIB override restrict	Indicated whether the site has restricted the use of DMS PARMLIBs to a set of specific data set names. If this option is not set, this is a major security loophole as any user can deactivate RACF processing in DMS and hence bypass RACF security.
DMS 1st qual backup profiles	The first qualifier used to backup discrete profiles.
DMS profile disk volume	The volume used to back up discrete profiles.
DMS call RACF non-indic	Indicates whether RACF is called for non-indicated data sets. Should be set (Y) on systems that have DFP.
DMS support for RACF	Indicates whether DMS supports RACF-protected data sets. If not set, DMS does not back up or restore RACF-protected data sets. If set, behavior depends on the 'process protected' setting.
DMS backup discretes	Indicates whether DMS does back up discrete profiles. Can be set to Y (save profiles for archive, but not for backup); N (save profiles for backup and archive), or F (never save profiles).
DMS predefined discrete OK	Indicates whether pre-defined discrete profiles are used on restore.
DMS process protected only	Indicates whether DMS processes RACF-protected data sets only (Y) or unprotected data sets too (N).
DMS NEWNAME allowed	Indicates whether a rename is allowed when a data set is restored. Should be set to N. If set to Y, this indicates a security exposure: DMS only checks access on the new (target) name, not the name being restored.
DMS test DASDVOL first	Indicates whether DMS is to use the RACF DASDVOL class.

The batch report is equivalent and is not shown.

Note: When precompiled DMS options are used, they might not be picked up by Security zSecure causing the program to fall back to the default settings. To avoid confusion, specify the DMS option settings in the parmlib configuration.

A second report DMSAUDIT shows the audit concerns identified.

EXITS - Exit and table report

Security zSecure reports on the exits used by various parts of z/OS, as well as the RACF tables. This report type works 'live' (with limited functionality) or by using a CKFREEZE file.

The RACF exits and tables can be reported on a live system. ACF2, CA-1, JES2, JES3, MPF, SMF, TSO, and WTO exits as well as I/O Appendages require a CKFREEZE file. More JES exits will be shown if the CKFREEZE file was produced by an APF-authorized Collect run. Dynamic exits require an APF-authorized run unless specific permits were given. HSM and SAMS:Disk (DMS) exits require an APF-authorized run.

Background

Exits are installation-defined programs that are called at well-defined points by MVS, system programs such as JES2 or RACF and ACF2, or third-party programs, in order to assist or alter the decision-making process of the calling program. An example of this is the RACF password encryption exit, ICHDEX01, which decides the type of password encryption to be used, and can even be used by an installation to implement a local encryption method.

Exits often execute in *key 0* which might grant the authority to alter MVS access control decisions.

Auditors should always review which exits are active; exits can be used to alter system security without changing the system's code or its visible parameters. Source code should be reviewed for all installation-written exits, and all changes should be monitored.

Auditing exits

Security zSecure can assist in auditing exits by showing the active exits and their contents. The following exit information can be audited:

- RACF and ACF2 exits
- SMF, TSO, JES2, JES3, DMS, HSM, MPF, WTO, and CA-1 exits.
- I/O appendages.
- Exits from the MVS 5.1 dynamic exit facility.

The input is taken from the actual in-storage control blocks that define whether an exit is used or not. For SMF exits, the decision whether an exit is taken or not can be defined separately for each subsystem. The SMF subsystem-dependent information is reported by another report type, see "SMFSUBOP - SMF subsystem report" on page 446. Exits IEFUSO and IEFUJP can even be activated on the job-class level in JES2. This is reported in the JES2 job-class report, see "JOBCLASS - JES2 Job Class report" on page 460.

The information displayed includes the *entry point* address, the *virtual storage area* where the entry point resides, and the leading 256 bytes of the exit, usually containing an eye catcher with a level indicator or copyright notice. In addition, an automatic *disassembly* is performed to see whether the exit returns a fixed return code 0, 4, or 8. The results of an instruction, string, and SVC scan performed by zSecure Collect are also shown.

The batch report to review the exits is CKALSXIT. The interactive report is called CKADSXIT.

Sample ISPF overview and detail displays for the exit report are shown in Figure 388 on page 503 and Figure 389 on page 504.

Figure 388. Exit Overview display

The overview display contains the following fields of interest.

Table 244. Exit and table overview - field descriptions

Field	Explanation
Complex	Name of the complex examined.
System	Name of the system examined.
Exits	The number of exits analyzed for the system.
Audit concerns	The number of exits for which audit concerns were identified.
Priority	The highest numerical audit priority identified.
Pri	Numerical audit priority assigned to the exit.
Program	The documented name of the exit (does not need to correspond to the actual module name).
Applic	The application owning the exit.
Subs	The subsystem name, if the application is JES2.
Dynamic exitname	The full name of the exit point, if the exit is dynamic.
Eff	Indicates if the module is called as a dynamic exit routine.
Description	A description of the function of the exit.
Means	The result from an automatic disassembly of the exit code.
Address	Address of the exit or table.
Where	Exit residency.
Key SP	The key and sub-pool of the storage area where the exit is located.
Jobname	The jobname of the address space owning the exit, if the exit resides in private storage.
Length	Approximate length of the exit module.
Exit at	Exit program name, module name and offset
InstrScan	Results of an instruction scan performed by zSecure Collect.

Table 244. Exit and table overview - field descriptions (continued)

Field	Explanation
Str	Results of a string scan performed by zSecure Collect.
Eye catchers	Start of the exit or table (nonprintables have been replaced by dots).
Audit concern	Audit concerns identified.

Select any of these for a detailed view of the exit, showing the location of the exits, the eye catchers in the first 256 bytes of the exit, and an interpretation of the exit based on a simple disassembly of the instructions.

```

Figure 389. Exit detail display

The detail display contains the following fields of interest:

Table 245. Exit and Table overview - field descriptions

Field	Explanation
Address	The address of the exit.
Where	Exit residency.
Key SP	the key and sub-pool of the storage area where the exit is located.
Jobname	The jobname of the address space owning the exit, if the exit resides in private storage.
Length	Approximate length of the exit module.
AM	Addressing mode.
Exit at	Module information and offset for the exit.
Appl	The application owning the exit.
Subs	The subsystem name, if the application is JES2.
Exitname	The full name of the exit point, if the exit is dynamic.
Description	The documented function of the exit.

Table 245. Exit and Table overview - field descriptions (continued)

Field	Explanation
Act	Indicates if a module is active.
Def	Indicates if the module has been added to a defined exit point.
Eff	Indicates if the module is called as a dynamic exit routine.
FiltTyp	Indicates the type of filter defined for the exit module.
JobFilt	The JOB filter pattern used to control if this module is called.
Stoken filter	The Address Space STOKEN used to control if this module is called.
InstrScan	Results of an instruction scan performed by zSecure Collect.
Str	Results of a string scan performed by zSecure Collect.
SVC scan result	Results of an SVC scan performed by zSecure Collect.
Eye catchers	Contents of the exit; non-printable characters have been replaced by periods.
Result	Result of disassembly. RC=*x* indicates the exit has a fixed return code *x*.
Audit concern	Audit concerns identified.
First 256 bytes of exit	The start of the exit is shown both in hex and text. Nonprintables have been replaced with periods in the latter.

A sample batch report is shown in Figure 390 on page 506.

Figure 393. Dynamic Exit Definitions Overview display panel (scroll right)

Table 246 lists the fields on interest on the Dynamic exit definitions overview report shown in Figure 392 on page 507 and Figure 393.

Table 246. Dynamic Exit Definitions - Overview field descriptions

Field	Description
Description	String explaining the function of the exit.
Dynamic exit name	Full name of the dynamic exit.
Exp	Indicates if the exit point module has been defined.
#Acti	Number of active exit routines for the exit point.
#Inac	Number of added, but inactive exit routines for exit point.
Amo	The required addressing mode for exit routines.
#Abnd	Number of abnormal endings an exit routine can have.
CAb	Indicates if the total number of abnormal endings for the exit routines is counted consecutively or cumulatively.
Fst	Indicates if the exit routine can be called in fast path mode.
Any	Indicates if the exit routine can be called in any key.
ExK	The storage key and execution key.
Ren	Indicates if the exit routine is required to be reentrant.
Sgl	Indicates if the exit can have only a single module associated with it at a given point in time.

To view detailed information for any of the exits included in the Dynamic definition overview display panel, type the **S** in the selection field for the report to open the detail display shown in Figure 394 on page 509..

DASDVOL - DASD volume report

Security zSecure allows you to view the Direct Access Storage Device (DASD) volumes connected to up to 32 systems; a CKFREEZE file for each of these systems is required. The report generated provides an overview of each of the DASD volumes on-line on at least one system; it can be edited to include all DASD volumes that are not on-line, but are referred to (e.g. in ICF catalogs).

This report requires a CKFREEZE file. A non-authorized zSecure Collect run suffices.

Note: unlike the other reports, which focus on resources or tables *per system*, the DASD volume report focuses on volumes, and shows the systems only relative to the DASD volumes connected.

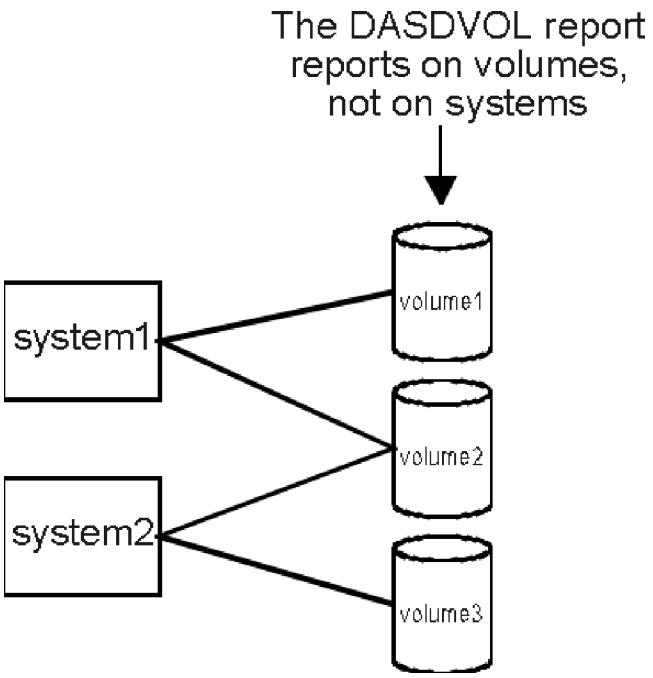

Figure 395. DASD Volumes

Background

DASD volumes can be accessed by one or more systems. This sharing is done by channels that connect systems to the control unit controlling the device where the volume is mounted.

Depending on the site, device numbers might or might not be the same across systems. Also, two systems showing a volume mounted with the same volume serial, do not need to share the same physical volume, even when the device numbers are the same. The former often happens if a site connects (merges) two different systems, the latter often happens if the site employs 'string switching' as a means to control change. For example, a complete DASD string is first used non-shared on a test system and is then connected to the production system. This separates test and production very well and leaves volume serials the same.

The DASD box serial number can be used to determine the sharing properties quite easily - but only more recent device types support this.

The values shown in the DASDVOL report are specified in parmlib member VATLSTxx, in the SMS control data set, the HCD, the MVSCP, and the IOGEN.

Auditing DASD Volumes

For Security zSecure to report on exposures reliably, it should know how volumes are shared across systems. The protection of the same data set can be different on different systems.

It is also checked that if two systems share the same volume, the volume is known to MVS as shared. If it is not, serialization (reserve and release processing) is not done when updating the volume, which can result in an undefined state of the volume when the two systems perform an update simultaneously.

The SMS management of DASD volumes is of importance too; data sets in the APF list that are specified without VolSer are only APF if they reside on an SMS managed volume.

The batch report to review DASD volumes is CKALVOLD. The interactive report is called CKADVOLD.

Figure 396 shows the DASD Volume overview display.

Figure 396. DASD Volume Report

The display contains the following fields of interest:

Table 247. DASD Volume Protection and Sharing - field descriptions

Field	Explanation
Pri	Relative audit priority.
VolSer	The volume serial of the DASD volume.
Man Fa Serial Id	The serial code of the volume, containing the code of the manufacturer, factory code, box serial number, and device tag.
Box type	The type of DASD volume, e.g. 3390-A28.
#	The number of systems on which the volume is mounted.
STO	Indicates whether the disk has the STORAGE mount-use attribute on any system.
PUB	Indicates whether the disk has the PUBLIC mount-use attribute on any system.
Audit concern	Audit concerns identified.

Figure 397 shows the DASD Volume detail display.

Figure 397. DASD Volume detail display.

Table 248. DASD Volume Protection and Sharing display - field descriptions

Field	Explanation
System	The name of a system to which the volume is connected. On the rest of the line, all fields following the system name, except for the audit concern, apply to that system only.
Devn	The device number of the DASD volume on the current system.
Attributes	Attributes for the volume on this system. This field can contain one or more of the following values: *IPL* (IPL volume) *MCAT* (contains the master catalog) *PAGE* (contains a page data set)
Shr	Indicates whether the system uses the DASD volume as a shared volume or not.
Mnt	Indicates whether the volume is mounted on the system.
SMS	Indicates whether the volume is SMS-managed on the system.
Use	The mount-use attribute of the volume; can be PRIVATE, PUBLIC, and STORAGE.
Unit	The unit type of the volume.

MOUNT - Effective UNIX mount points

The MOUNT report shows the effective UNIX mount points. A full CKFREEZE read is required, and the CKFREEZE must have been made with the UNIX=Y parameter.

This report requires a CKFREEZE file and shows more information if the zSecure Collect run was APF-authorized.

Background

z/OS UNIX files are physically contained in an hierarchical file system (HFS) or zSeries file system (zFS) data sets. A UNIX file system consists of a directory tree in which files are located. A file system is made accessible by mounting it, for example, by assigning it a position in the existing directory tree (mounting it over that directory--this hides the previous contents of that subtree). The root directory of the file system is then located at the mount point, and its subdirectories form the new subtree.

A device number is associated with each mount point (mounted file system). Together with the *inode* number which identifies a file within a file system this yields a key to a file. Starting with OS/390® Version 2 Release 9, it is possible to share file systems across a sysplex. In that case the file system is owned by one system, and others can talk to it via the Coupling Facility. Access to the DASD the file system resides on is not needed by the other systems, they refer to a specific device number.

An automount point is a special mount point where user file systems get dynamically mounted when a reference is made to a file in them. They can also be dynamically unmounted when no references are made for some amount of time.

This information can be obtained with the OMVS command **df** or the D OMVS,F operator command.

Auditing UNIX mounts

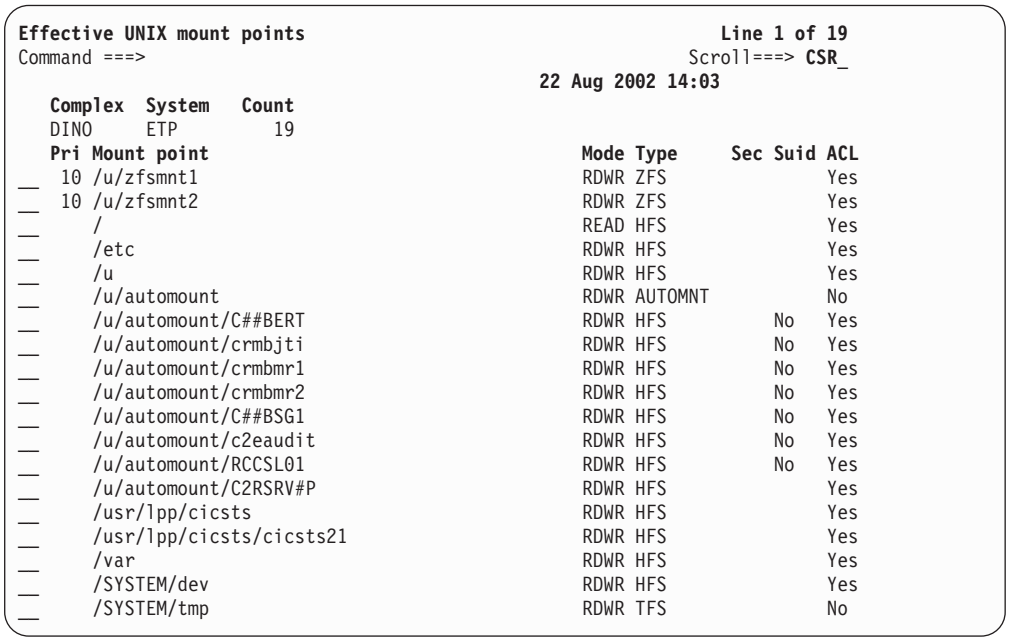
There are several mount options that are relevant for security. For instance, a file system can be mounted in such a way that the UNIX security settings are used for protection, or that they are ignored. Also the **setuid** bits can be ignored, for example, the program runs under the users own uid instead of under the program file owner's uid. A file system can also be mounted in read-only mode.

A file system might or might not support ACLs, or it might not know about ACLs. In a sysplex environment with some systems that support ACLs and some that do not, files with ACLs are inaccessible (except perhaps for the file owner or a superuser) from the downlevel systems (if they know of ACLs) if the FSSEC class is active on an up-level one.

zFS file systems have an additional NBS (New Block Security) option for clearing new blocks before they are linked to a file. This option is more or less the opposite of the EOS (Erase On Scratch) option that clears blocks when they are freed. The NBS option ensures that blocks that contain data from previous files they belonged to cannot be read if the system crashes between the moment the block is linked to a file and the moment the block is written. For security, the NBS option must be enabled to prevent someone from accessing parts of protected data. If the option is not enabled, an audit concern is issued.

The batch report to audit UNIX mount points is CKALSMNT. The interactive report is called CKADSMNT.

UNIX mount points are shown in the following figure.



```

The preceding figure contains the following fields of interest.

Table 249. Effective UNIX mount points - field descriptions

Field	Explanation
Audit concern	**Audit concerns identified**
Complex	The complex name.
System	The system name.
Count	The number of mount points.
Pri	Relative audit priority.
Mount point	The absolute pathname of the mount point.
Mode	The mode in which the file system is mounted: READ (read-only) or RDWR (read/write).

Table 249. Effective UNIX mount points - field descriptions (continued)

Field	Explanation
Audit concern	**Audit concerns identified**
Type	The file system type which can be any of the following: **ZFS** zSeries file system (based on DCE LFS Episode file system). **AUTOMNT** Automount point for dynamical file system mounts/unmounts **CINET** File system that handles requests for AF_INET sockets. **DFSC** Distributed global file system (under DCE). **HFS** Hierarchical (local) file system. **INET** Like CINET but assumes SecureWay Communications Server. **NFS** Network (remote) file system. **TFS** Temporary file system. **UDS** File system that handles requests for AF_UNIX sockets.
Sec	Whether the file system is mounted with the SECURITY attribute. If not, any user can access and change any file in it.
Suid	Whether the file system is mounted with the SETUID attribute. Setuid, setgid, APF, and program control attributes for files are only honored if this is the case.
ACL	Whether the file system supports Access Lists.
NBS	New Block Security. This option only applies to zFS file systems. When enabled, disk blocks are physically cleared before they are linked to a file.
RO_Secl	The assumed, read-only security label. See also “READONLY_SECLABEL” on page 1106.
File system name	The name of the file system.
Dataset	The name of the MVS data set that contains the file system.
OwnCompl	The complex the system that owns the file system mounted is in.
OwnSyst	The system that owns the file system mounted.
Device	The UNIX device number for the mounted file system.
Volser	The volume serial of the MVS data set with the file system.
RWS	A flag field that indicates whether the file system is sysplex-aware. If True, the file system was mounted with sysplex_mode=on or with PARM(RWSHARE).

Table 249. Effective UNIX mount points - field descriptions (continued)

Field	Explanation
Audit concern	**Audit concerns identified**
Plex mode	A field that indicates the zFS sysplex status. The possible values are: • **Noshare**: zFS is not in a shared file system environment. • **Admin-only**: zFS is in a shared file system environment but is not sysplex-aware. • **On**: zFS is in a sysplex-aware environment with sysplex=on. • **Filesys**: zFS is in a sysplex-aware environment with sysplex=filesys.

Select any row for a detail view of a particular mount point.

The detail display contains the following fields of interest:

Table 250. Effective UNIX mount points - field descriptions

Field	Explanation
Complex name	The name of the complex.
System name	The system name.
Mount point	The absolute pathname of the mount point.
UNIX device number	The UNIX device number for the mounted file system.
File system mode	The mode in which the file system is mounted: READ (read-only) or RDWR (read/write).

Table 250. Effective UNIX mount points - field descriptions (continued)

Field	Explanation
File system type	The type of file system mounted.
File system name	The name of the file system (for HFS equal to data set name)
Mounted with SECURITY	Whether the file system is mounted with the SECURITY attribute. If not, any user can access and change any file in it.
Mounted with SETUID	Whether the file system is mounted with the SETUID attribute. Setuid, setgid, APF and program control attributes for files are only honored if this is the case.
File system supports ACLs	Whether the file system supports Access Lists.
New Block Security	This option only applies to zFS file systems. When switched on, disk blocks are physically cleared before they are linked to a file.
Read-only security label	The assumed, read-only security label. See also "READONLY_SECLABEL" on page 1106.
Read/Write share	A flag field that indicates whether the file system is sysplex-aware. If True, the file system was mounted with sysplex_mode=on or with PARM(RWSHARE).
Sysplex mode	A field that indicates the zFS sysplex status. The possible values are: • **Noshare**: zFS is not in a shared file system environment. • **Admin-only**: zFS is in a shared file system environment but is not sysplex-aware. • **On**: zFS is in a sysplex-aware environment with sysplex=on. • **Filesys**: zFS is in a sysplex-aware environment with sysplex=filesys.
Relative audit priority	Relative audit priority.
Audit concern	Audit concern identified.
Complex that owns file system	The complex that owns the system that the file system is mounted in.
System that owns file system	The system that owns the file system mounted.
Data set name	The name of the MVS data set that contains the file system.
Volume serial	The volume serial of the MVS data set with the file system.
DASD box serial number and ID	The serial number of the volume containing the manufacturer, factory code, box serial number and device tag.
Size of block in bytes	Size of a block of the zFS file system in bytes (normally 8192).
Size of fragment in bytes	Size of a fragment of the zFS file system in bytes. Multiple files can share a logical block if they are smaller than (block size - fragment size). (1k,2k ... up to block size).

Table 250. Effective UNIX mount points - field descriptions (continued)

Field	Explanation
Size of aggregate in blocks	The size in blocks of the aggregate. Normally the number of blocks that fit in the primary allocation.

For a thorough look at UNIX file protection look at the following reports: "APFPROT - Authorized Programs reports" on page 328, "GLBW - Globally writable data reports" on page 348.

SENSITIVE - Sensitive Data Set report

The sensitive data set report describes the system sensitive data sets for each system.

This report requires a CKFREEZE file and shows more information if the zSecure Collect run was APF-authorized.

The sensitive data set reports list data sets on the system that are considered sensitive and pose a threat if they are tampered with. There are 4 reports available. A report for the APFlist, the linklist, the LPA list, and a combined report which lists all sensitive data sets. These reports do not give information about how the data sets are protected, nor if they are sufficiently protected.

For RACF systems you can have a look at the RACF RESOURCE category for a report on the protection of these data sets (SENSITIVE PROF), and a list of users with access to them (SENSITIVE TRUST). In addition to these reports the command VERIFY SENSITIVE is available to check the protection, and if necessary generate the RACF commands needed to ensure adequate protection.

Background

The system sensitive data sets are those data sets that need adequate protection to ensure system operation and protection is not disturbed. This includes the APFlist, the linklist, the LPAlist, system parameter libraries, audit trail data sets, system command and system program libraries, page and dump data sets, etc.

The sensitive data set report lists all system-sensitive libraries, and all libraries available on this system but sensitive on another system. The report lists the data sets and the protection required to meet the CS-1 (Commercial Security 1) protection profile from the U.S. Federal Criteria and the draft ISO and Common Criteria. Security zSecure assigns each data set a *sensitivity*, which describes the reason why the data set should be protected, and a *risk*, which describes the lowest access level considered an exposure.

You can add your own data sets by means of the SIMULATE SENSITIVE command (see "SIMULATE" on page 911). You can use SIMULATE SENSITIVE PROCLIB to flag integrity problems for JES2 proclibs used for batchjobs.

Auditing Sensitive Data Sets

The following considerations apply when auditing system-sensitive data sets:

- Ensure the APFlist is up-to-date, for example, all libraries named in the APFlist (and the linklist, if it is authorized) should exist. If a library does not exist, a user could create his own data set, and then rename it to have the name of the missing APF library, thus creating his own authorized programs. In the output of the Sensitive Profiles report such data sets are marked '**notfnd**'.

- Ensure all sensitive data sets are adequately protected and audited. On RACF systems, you can use the Sensitive Trustees and Sensitive Profiles reports to find problems, and the VERIFY SENSITIVE command to fix them.

The batch report to review the sensitive data sets is CKALSENS. The interactive reports are called CKADSEN0 (concise) and CKADSENS (detailed).

The sensitive data sets report can be customized by specifying that all JES2 job proclibs are to be considered sensitive. When using the STATUS AUDIT menu, you can check the option on the customization panel. When generating a report with a batch job, you can include a SIMULATE SENSITIVE PROCLIB command.

After selecting the combined report, the following display appears:

```

Figure 399. Sensitive data set display

Table 251 describes the fields of interest in this panel.

Table 251. Sensitive data set display panel - fields of interest

Field	Explanation
Complex	The name of the complex examined.
System	The name of the system examined.
Sensitive data sets	The number of sensitive data sets.
Audit concerns	The number of sensitive data sets for which audit concerns were identified.
Priority	The highest priority for any sensitive data set.
Pri	Numerical audit priority.
Sensitivity	The sensitivity type of the data set. See the fields SENSITIVITY and RISK in “SENSDSN: Sensitive Data Set Names” on page 1255 for a complete list of sensitive datasets and with which access they can be compromised.
Dataset	Data set name.
Volser	Volume serial (blank for VSAM data sets).
Risk	The lowest access level considered a risk.
Audit concern	Audit concerns identified.

Note: The sensitive data set report generates four displays, each slightly different. The preceding display includes the combined display, describing all sensitive data sets. The other displays describe the APFlist, linklist, and the LPAlist. The main difference between the displays is the type of data sets described and the sort order. Also, some fields from the preceding table might be absent and some fields in the following table might be present.

Field	Explanation
APF	Indicates whether the data set is considered APF-authorized on this system. The data set can be on the APF list, on the LPA list, or on the authorized linklist.
APFlist	Indicates whether the data set is on the APF list on this system.
LPA	Concatenation number in the LPA list on this system.
Lnk	Concatenation number in the linklist on this system.

Field	Explanation
Lnkauth	Indicates whether the linklist is authorized (LNKAUTH=LNKLIST) or not.

All fields mentioned in the previous two tables can also be found on the detail display.

AU.C Change track

The interactive component of the Change Tracking system is an ISPF application available under MVS/TSO.

Use Change Tracking to create a verified information base of sensitive RACF profiles, attributes, and other system settings and report on any changes in this information base. The report lists the differences between records in the verified collection and the current system configuration. From the report, you can confirm the changes and update the information in the verified collection with the new information or reject the changes.

The security database records included in the verified collection are data sets that protect APF-authorized libraries and others that your site considers sensitive. To review the list of sensitive resources, see “REPORT_SENSITIVE: Sensitive data sets by profile ” on page 1240. You can monitor other system settings like changes to the list of APF authorized libraries and changes to the RACF Class Descriptor Table. You can track changes to most items that Security zSecure can report information about.

Information is fed to the Change Tracking system by batch housekeeping, which runs Security zSecure to extract system information. You can generate reports from multiple systems, although Change Tracking normally runs on one central system.

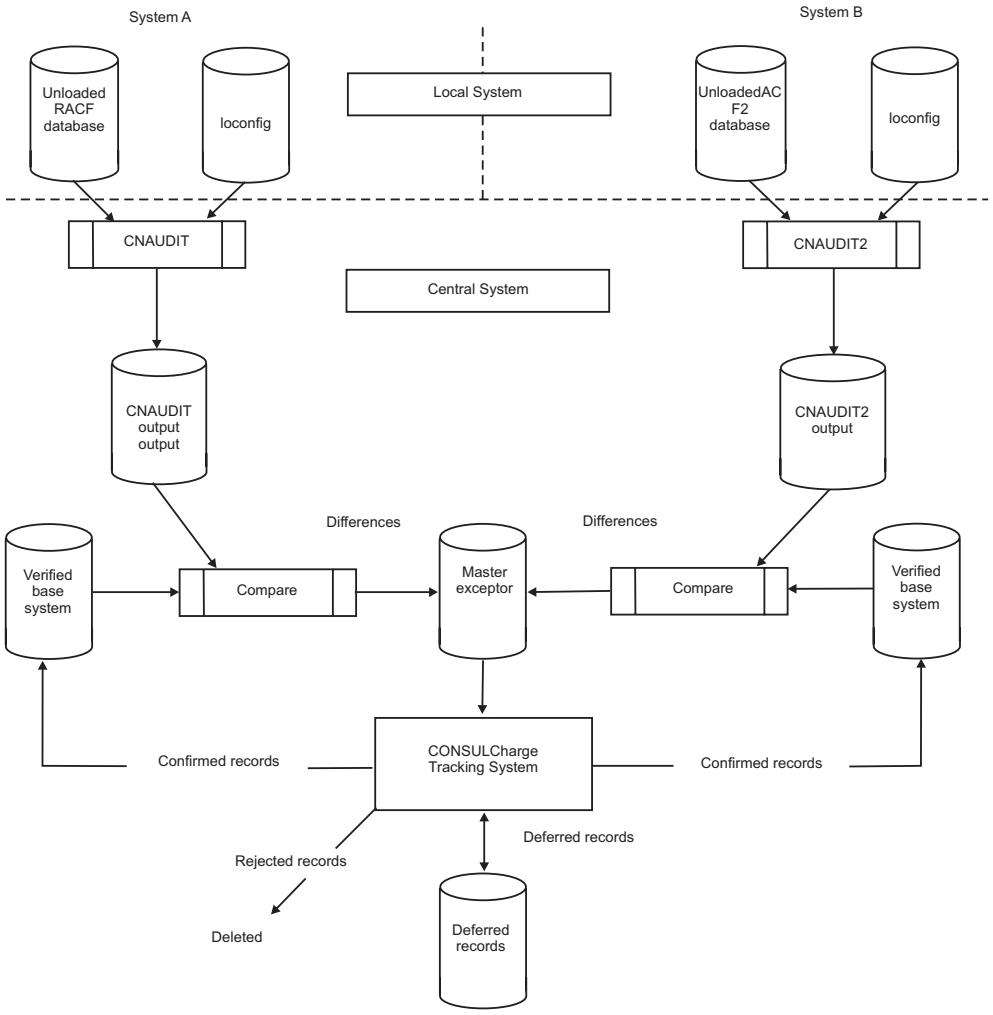

Figure 400. Change Tracking system

The type of information you can monitor depends on the IBM Security zSecure products that are available at your site.

After selecting the **AU.C** Change Track option, a screen is displayed showing all systems that changes are reported for and the date that the batch housekeeping component of Change Tracking ran for each system. The following panel is displayed:

```
 Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - Change track      Row 1 to 2 of 2
Command ===>                                                Scroll ===> CSR

Enter (E)xceptions or (D)eferred
_ Only select site defined message ids.

  System ID     Date of last run      Days since last run
_  C#M4         14 AUG 2000             1
_  C#M5         14 AUG 2000             2                  *** Warning ***
****************************** Bottom of data ********************************
```

The batch housekeeping component of Change Tracking performs the comparison between the verified base and the current system settings for each system. It is important to run this job daily. If the housekeeping has not run in the previous day for a particular system a `*** Warning ***` message is shown on the right hand side of the display, on the same line as the system name. If you see this message, contact the person who maintains Change Tracking at your site to find out why the housekeeping job did not run.

When you select **Only select site defined message ids**, changes reported because of IBM Security zSecure defined message IDs are not displayed.

The **D** (deferred) action command on the CT system display shows all deferred changes. Processing is similar to **E** (exceptions) processing with the following two differences:

- Only changes in deferred status are displayed
- The D action command is not available. You can not defer a change record that is already in deferred status.

The **E** (exception) action command opens a panel showing all exceptions as shown in Figure 401 shows all exceptions:

```

```

Figure 401. Change Tracking panel - Detail view

The display has three fields:

Field	Explanation
Msg	The message ID associated with the record.
Description	The description of the message ID.
Details	The details of the change.

A message ID is a 6 digit number preceded with an C or U, describing a record type. Each record type describes a different sort of change to the system. For example, a record that has message id *U000001* can be defined to represent the RACF system special attribute having been added or deleted from a user ID. For instructions on defining messages, see “SE.C SETUP - Change track” on page 1668.

The Description shows details of what the message id means and whether it was an addition or a deletion.

The Details give further information about the record. These vary from message to message.

It is worth bearing in mind that the Change Tracking system reports changes to the configuration system by comparing how the system is currently configured to the verified base. This means that information about the person who made the change is not available. This information is likely to be in the SMF audit trail, which Change Tracking does not read.

Commands on the Change Tracking display

On the Check changes display you can enter the line command (/). The line command displays a pop up window that lists the other line commands shown in the following table.

Command	Meaning	Explanation
A	Accept change	Confirm that the change is correct and authorized and add the record to the verified base.
D	Defer change	Defer the change for future action while you investigate it further or until the situation can be remedied.
S	Show additional information	Show detailed information about the change.
R	Reject change	Reject the change. The record is not added to the verified base. If the situation that caused the record to be reported has not been corrected before the next run of the Change Tracking housekeeping, the change is reported again.

The A, D and R line commands opens a pop-up window, so a change request number or comment text can be entered. Additionally , the R(eject) command opens a pop-up window which suggests the appropriate action to take. A CKGRACF record is written for every Accept, Defer or Reject command that is run.

The primary command ACCEPT ALL accepts all changes. This processing can take a while. For an initial CT run, set the INIT#CT parameter for CT collection job CKAJTSYS to EQ so that all exceptions are written directly to the verified base. The SMF record is only written if IBM Security zSecure Admin is available.

Batch auditing

This manual gives most attention to the Security zSecure ISPF interface. However, the product can also be used in batch mode. The following list describes several ways to use Security zSecure in batch mode. See "Predefined CARLa scripts" for an overview of sample reports.

- The Security zSecure main menu options **AU.L** Libraries, **AU.S** Status, and **EV** Events each have a processing option called either **Run query in foreground or background** or **Run in background**. Selecting a background run enables you to submit a batch job generating the report types selected.
- Main menu option **CO** Commands can be used to submit custom queries or queries from CARLa libraries. The SCKRCARL data set contains many batch reports that can be used or tailored.
- You can create your own JCL submitting a Security zSecure job. The JCL samples in the SCKRCARL data set, or the JCL generated by Security zSecure when you submit a background job can be a good starting point.

  In your own JCL, you can use the INCLUDE command to imbed CARLa scripts from the SCKRCARL data set or your own libraries. You can also use the full Security zSecure language (CARLa) to create your own custom reports.

Predefined CARLa scripts

This section discusses the interactive ISPF and batch reports available in the SCKRCARL library. For information on the naming conventions for CARLa scripts, see "Naming convention" on page 706

Interactive reports

The following interactive (ISPF) system reports are available (these start with CKAD or CKRD):

Report	Meaning
CKAD@MO	Audit concerns from system reports that do not need a CKFREEZE (used to build audit concern overview)
CKAD@XO	Audit concerns from system reports that require a CKFREEZE (used to build audit concern overview)
CKADSCON	System Console Definitions.
CKADSCSM	Globally Modifiable Common Storage Map.
CKADSD80	VM settings audit concerns (80 columns wide). Automatically included by CKRDSD80.
CKADSDMS	DMS system options.
CKADSENS	Sensitive data sets, detailed report.
CKADSEN0	Sensitive data sets, concise report.
CKADSIOA	System Authorized I/O Appendage Table.
CKADSIP	Communications Server IP reports
CKADSIPL	IPL parameters display.
CKADSJC0	JES2 job class parameters, concise report.
CKADSJCL	JES2 job class parameters, detailed report.
CKADSMFS	SMF subsystem settings.
CKADSMNT	Effective UNIX mount points.

Report	Meaning
CKADSMSG	System message-specific data from the Message Processing Facility.
CKADSPC	Program Calls, detailed report.
CKADSPC0	Program Calls, concise report.
CKADSPPT	Program Property Table
CKADSSC0	Subsystem Communication Vector Tables, concise report.
CKADSSCT	Subsystem Communication Vector Tables, detailed report.
CKADSTAP	Tape protection settings (RACF)
CKADSVC	Supervisor Calls, detailed report.
CKADSVC0	Supervisor Calls, concise report.
CKADSVSM	System Virtual Storage Map.
CKADSXIT	Exit and table overview.
CKADSY80	MVS settings audit concerns display (80 columns wide). Automatically included by CKRDSY80.
CKADVOLD	DASD volume protection and sharing.
CKRDSD80	VM settings audit concerns (80 columns wide). Automatically includes CKADSD80.
CKRDSY80	MVS settings and options (80 columns wide). Automatically includes CKADSY80.
CKRDSYSM	System-wide SMF options and settings.

Batch reports

The following batch system reports are available (these start with CKAL, CKAV or CKRL):

Report	Meaning
CKAL$ALL	Collection of all system and many RACF-specific reports.
CKAL$MD	Collection of all system reports that do not require a full CKFREEZE read or RACF database .
CKAL$XD	Collection of all system reports that do require a full CKFREEZE read (but no RACF database).
CKAL@ALL	Overview of audit concerns from all system and many RACF-specific reports.
CKAL@MO	Audit concerns from system reports that do not need a CKFREEZE (used to build audit concern overview)
CKAL@XO	Audit concerns from system reports that require a CKFREEZE (used to build audit concern overview)
CKALSCON	System console definitions.
CKALSCSM	Find globally writable common storage areas (reports on error conditions).
CKALSD13	VM settings audit concerns (132 columns wide). Automatically included by CKRLSD13.
CKALSD80	VM settings audit concerns (80 columns wide). Automatically included by CKRLSD80.
CKALSDMS	DMS system settings.

Report	Meaning
CKALSENS	Four reports on system-sensitive data sets: LPAlist, linklist, APFlist, and all system-sensitive data sets.
CKALSIOA	Authorized I/O appendages.
CKALSIP	Communications Server IP reports
CKALSIPL	IPL parameters listing.
CKALSMNT	Effective UNIX mount points.
CKALSJCL	JES2 job class settings.
CKALSMFS	SMF subsystem options.
CKALSMSG	Message-specific data from the System Message Processing Facility.
CKALSPC	Six reports on Program Calls, showing an overview of audit concerns, a mapping of Linkage Index to Entry Table, a mapping of Entry Table owner to Linkage Index, a system-wide PC routine overview, a non-system-wide PC routine overview, and a detailed view of all PCs sorted by audit priority.
CKALSPPT	Program Property Table.
CKALSSCT	Subsystem Communication Vector Tables.
CKALSTAP	Tape protection settings (RACF)
CKALSVC	Three reports on the SVC table, showing an overview of audit concerns, a summary of the current state of the SVC table, and a detailed view of all SVCs sorted by audit priority.
CKALSVSM	System Virtual Storage Map.
CKALSXIT	Exit and table report.
CKALSY13	MVS settings audit concerns report (132 columns wide). Automatically included by CKRLSY13.
CKALSY80	MVS settings audit concerns report (80 columns wide). Automatically included by CKRLSY80.
CKALVOLD	DASD volume protection and sharing.
CKAVRWWD	Generate UNIX commands to make directories **not** world-writable
CKRLSD13	VM settings audit concerns (132 columns wide). Automatically includes CKALSD13.
CKRLSD80	VM settings audit concerns (80 columns wide). Automatically includes CKALSD80.
CKRLSY13	MVS system settings and options, formatted in 132 columns. Automatically imbeds CKALSY13.
CKRLSY80	MVS system settings and options, formatted in 80 columns. Automatically imbeds CKALSY80.
CKRLSYSM	System-wide SMF options and settings.
C2AL$ALL	Collection of all system and many ACF2-specific reports.

We advise you to run the overall report, CKAL$ALL , at least once. You are then able to decide which reports are useful at your installation, and which sample reports must be edited.

Chapter 6. Library Audit Guide

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

Security zSecure provides library update reports that are used to find and display changes to members of partitioned data sets, as well as changes to a select few sequential data sets and VSAM data sets that you have designated as critical. It handles data sets used on a single system, data sets on shared DASD, and SMS-managed data sets within a sysplex. The reports handle cataloged data sets as well as non-cataloged data sets. The source for these reports are multiple CKFREEZE files for a single system or sysplex; changes can be tracked in the time frame between the dates the earliest and latest CKFREEZE files were generated. (How to create the correct type of CKFREEZE files is discussed later.)

When generating a library update report, Security zSecure starts by tracking the physical data sets over time. It takes into account shared DASD volumes, duplicate volume serials, and duplicate data set names. Tape data sets are supported as well. A simple case of non-SMS-managed volumes is illustrated in Figure 402.

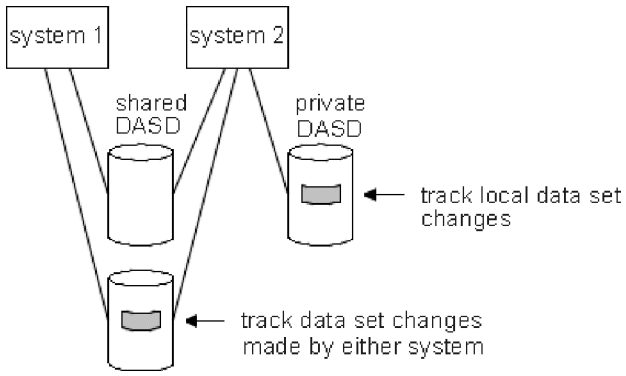

Figure 402. Tracking of data sets

In Figure 402, Security zSecure uses CKFREEZE files from either system to track changes to the data sets on shared DASD and CKFREEZE files from system 2 to track changes to data sets on private DASD.

Security zSecure is also able to track changes to a data set as it is moved from one SMS-managed DASD volume to another. It takes the sysplex name into account; it is safe to mix CKFREEZE files from different sysplexes. Figure 403 on page 530 illustrates tracking SMS-managed data sets.

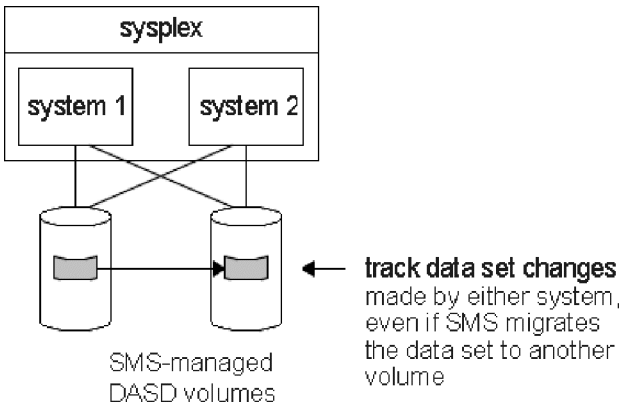

Figure 403. Tracking of SMS-managed data sets

If a data set is moved from a non-SMS-managed DASD volume to an SMS-managed volume, Security zSecure assumes the data set was migrated, and issues warning message CKR0472. This assumption might be false if a data set is deleted and a data set of the same name is later cataloged to an SMS-managed volume.

When the history of the data sets has been determined, Security zSecure tracks changes to data set members. For successive CKFREEZE files that describe the member, the member is compared using a checksum; if no checksum is available, the directory information describing successive members is compared. (A checksum is computed by zSecure Collect, as described later.) In this way, Security zSecure is able to determine during which periods the member was unchanged, and approximately when the member was changed. This is illustrated in Figure 404.

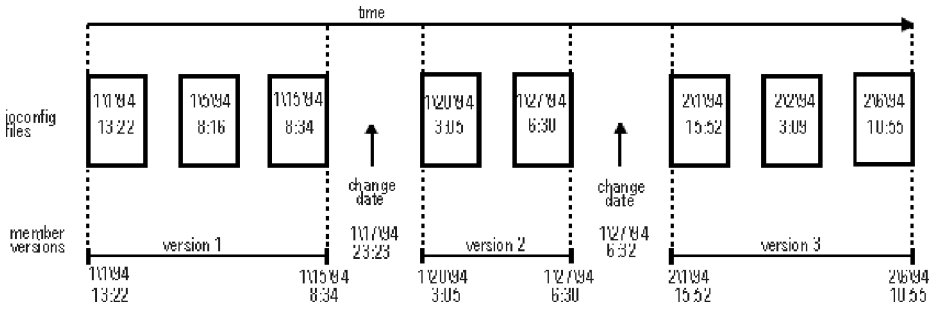

Figure 404. Data set member changes

In Figure 404, Security zSecure splits the history of the member into three periods during which the member was unchanged, each with a start-date and an end-date. Note that the changes to the member were made at some time during the gap between two measurements. In the Security zSecure library update report, a data set member unchanged during a period of time is called a member *version*. Security zSecure reports on these member versions, and the number of changes made over time; for each member version, directory data, checksum data, and instruction/SVC/String scan data can be reported.

All this is more or less true for sequential data sets as well. Checksum data is used from successive CKFREEZE files that describe the data set to determine whether the data set has changed, and approximately when. Of course, since sequential

data sets do not have directories and are not subject to things such as instruction scans, the amount of additional data to be reported on is much more limited than for partitioned data sets.

Preparing CKFREEZE files

The library update report uses CKFREEZE files as its data source. Unlike the other Security zSecure report types, which use one CKFREEZE file per system, the library update report can use several CKFREEZE files per system or sysplex.

When you start using the library update report, your installation procedures might require alteration to maximize the number of generations of CKFREEZE files that are available and online.

You can add CKFREEZE files using the SETUP FILES panel (**SE.1**). New CKFREEZE files can be created using the SETUP NEW panel (**SE.2**), or using the LIBRARY FREEZE panel (option **AU.L.0**).

Figure 405 illustrates how to create a new CKFREEZE file and add it to an existing **Set** of Security zSecure input files. First, go to the LIBRARY FREEZE panel (**AU.L.0**).

```
  Menu  Options  Info  Commands  Setup
--------------------------------------------------------------------------------
                          zSecure Suite - Audit - Libraries Freeze
Command ===> ____________________________________________________________

_  System      - All system sensitive libraries
_  Application - Libraries specified below

Library data set names (fully qualified, no quotes)
Data set name 1 . . . . _____________________________________________
Data set name 2 . . . . _____________________________________________
Data set name 3 . . . . _____________________________________________
Data set name 4 . . . . _____________________________________________
Data set name 5 . . . . _____________________________________________
Data set name 6 . . . . _____________________________________________
Data set name 7 . . . . _____________________________________________
Data set name 8 . . . . _____________________________________________
Data set name 9 . . . . _____________________________________________
Data set name 10  . . . _____________________________________________
```

Figure 405. Library Freeze Menu

In this panel, you can specify the data sets to be frozen. The panel offers the following options:

SYSTEM	Create digital signatures for all system sensitive libraries. This option can be combined with option *APPLICATION*.
APPLICATION	Create digital signatures for the data sets specified on the lower half of the screen. This option can be combined with option *SYSTEM* to create signatures for system sensitive libraries *and* user-specified libraries.

Note that you cannot use this panel to specify sequential data sets for which checksums should be calculated. You cannot do that because this function is typically used in a different way for sequential data sets. For partitioned data sets, changes to members are expected over time, and the main purpose of the library audit function is to monitor these changes. On the other hand, the physical

sequential data sets and VSAM data sets that are important enough to monitor generally do not change much, if at all. The main purpose of calculating a checksum for these data sets is to provide a way to verify that the data set has not been tampered with, typically just before offloading the data to tape.

```
 Menu  Options  Info  Commands  Setup
--------------------------------------------------------------------------------
                          zSecure Suite - Audit - Libraries Freeze
Command ===> ____________________________________________________________________

Complete this panel and press ENTER

Optional checksum password   ===> ____________________________________________

Scan string       - List of character values to search in libraries
_____________________________________________________
Scan SVC          - List of supervisor call numbers to search in libraries
_____________________________________________________

Note: type commas between values in the list, e.g. 'SECURITY','BYPASS'
```

Figure 406. Library Freeze Options panel

Optionally, you can supply a checksum password. This can be used to provide virus detection capabilities. See "zSecure Collect command reference" on page 1612. The default for the checksum password is taken from the site-specific string in the CKRSITE module.

Warning: If you change the checksum password, or if you create some CKFREEZE files with checksum passwords and some without, then these files cannot be combined for a library update report.

Additionally, you can specify one or more search strings and calls to one or more Supervisor Service Calls (SVCs) to be searched for in the members for which digital signatures are computed. A Supervisor Service Call (SVC) is a call to a part of operating system that operates in Supervisor state even though called from an unauthorized program.

After you have specified the freeze options, and if either SYSTEM or APPLICATION or both are selected, the data set where the CKFREEZE file is to be stored is created (see Figure 407 on page 533). If the CKFREEZE file already exists, you are prompted to reuse the existing data set or allocate another one.

```
                        zSecure Audit - Setup - New files
Command ===> ____________________________________________________________

CKFREEZE file not found. Change dataset name, or specify allocation parameters

 Dataset name . . . SIGNATUR.CKFREEZE_____________________________________

Allocation parameters to create new dataset:
 Volume serial  . . ______      (Blank for authorized default volume)
 Generic unit . . . ________    (Generic group name)
 Space units  . . . TRKS____    (KB, TRKS, or CYLS)
 Primary quantity . 30______    (In above units, press HELP for suggestion)
 Secondary quantity 30______    (In above units)

 Record format  . . VBS__       (VB or VBS)
 Block size . . . . 27998__
 Logical Record Len X______     (X or maximum record length)

Press ENTER to allocate dataset, press END to stop processing
```

Figure 407. Library Freeze Allocate Data set

On this display, the target data set is specified in which the CKFREEZE file is written. Enter the data set name and press ENTER. If the data set exists, the next panel is displayed; otherwise, you are prompted to correct the data set name or enter allocation parameters. If you press ENTER again without changing the data set name, the data set is allocated. Reasonable allocation parameters are about 2 MB per online DASD volume.

The panel in Figure 408 can be used to review, edit, or submit the JCL. The menu options are not discussed in detail.

```
                        zSecure Audit - Submit menu         Please submit job
Option ===> ____________________________________________________________

1  Browse       Browse JCL
2  Edit         Edit JCL
3  Submit       Submit JCL for execution
4  Cancel       Do not submit the JCL

Job statement information:  (Verify before proceeding)
> //ADGRANTI JOB ,FREEZE,TIME=(10),MSGCLASS=A,NOTIFY=ADGRANT,CLASS=P,_____

> ________________________________________________________________________
```

Figure 408. Library Freeze Submit JCL

After the job has been submitted (e.g. using option **3**), the CKFREEZE file is generated. Wait until the job completes before adding the new CKFREEZE file to a new or existing **Set** of input files. (You can use Security zSecure with an existing **Set** of input files while the CKFREEZE file is generated in the background.) The panel as shown in Figure 409 on page 534 informs you that a job is running, and that the new CKFREEZE file can be used in a new or existing Set of input files, as soon as it has finished. It can be left by pressing ENTER or EXIT.

```
                        zSecure Audit - Setup - New
Command ===> ____________________________________________________________

Datasets will be ready for use after the job completes

Please add any new dataset to a Set of Input Files for use by
zSecure
```

Figure 409. Library Freeze Job Submitted

Interactive Audit Libraries processing

The Audit Libraries application is available using main menu option **AU.L** Audit Libraries. This application allows you to specify selection criteria and then process several CKFREEZE files in the foreground, or submit an equivalent batch job, resulting in a report showing the changed libraries or members. The Audit Libraries panel is displayed in Figure 410.

```
  Menu   Options   Info   Commands   Setup          StartPanel
------------------------------------------------------------------------------
                      zSecure Audit - Audit - Libraries
Command ===> ____________________________________________

0    Freeze          Calculate new digital signatures
1    Lib all         Overview of all libraries
2    Lib changes     Overview of all libraries with changes
3    Status          Show member status
4    Changes         Identify members with changes
5    Scan            Show members flagged by SCAN function
6    Duplicates      Identify identical members
7    Application     Members summarized by application
8    Prefix          Members summarized by member prefix (component code)
9    PTF - ZAP       Members touched by PTF or ZAP
```

Figure 410. Audit Libraries main menu

This first panel offers the following options:

Table 252. Audit Libraries panel - available options

0 FREEZE	Create a new CKFREEZE file. This option has been described in the previous section.
1 LIB ALL	Overview of all libraries and sequential data sets described by the CKFREEZE files. No detail information is included.
2 LIB CHANGES	Overview of the changes in all data sets described by the CKFREEZE files. No detail information is included.
3 STATUS	Show the status of selected members and sequential data sets on or near a particular date.
4 CHANGES	Show all selected changed members and sequential data sets from a specified range of time.
5 SCAN	Show members flagged by the instruction scan or string scan functions.
6 DUPLICATES	Identify identical members. Identical members can be in different libraries and can have different names. Can identify identical sequential data sets too.
7 APPLICATION	Summarize members by application, based on member name prefix.

Table 252. Audit Libraries panel - available options (continued)

8 PREFIX	Summarize members by member prefix, often the product identification.
9 PTF - ZAP	Summarize members by ZAP or PTF id.

For options 2, 4, and 6, CKFREEZE files with digital signatures are required. These files are created with option **0: Freeze**. Alternatively, you can create this type of CKFREEZE file by running zSecure Collect in batch with the CHECK=YES parameter specified. See "zSecure Collect command reference" on page 1612.

For option 9, a CKFREEZE file with IDR information is required. This information is automatically available when CHECK=YES is in effect. Otherwise, you need to specify the zSecure Collect IDR=YES parameter.

For additional information on these options, press PF1 or enter HELP to open the help panel

Selection and options

In this section, the common selection, exclude, and processing options for Audit Libraries reports are discussed. In the next section, the individual reports are discussed.

Select option **3** or **5** to view the common selection panel shown in Figure 411. If you select any of the other options, the resulting panel has fewer fields.

```
                        zSecure Audit - Audit - Libraries Selection
Command ===> ____________________________________________________________________

Select libraries and members that fit all of the following criteria:

Dsname . . . . . _____________________________________________ (EGN mask)
Member name  . . . . . ________
Disk volser  . . . . . ______
Signature status . . . _  Program signed    _  Verification failed
Status at date . . . . __________                    (ddmmmyyyy or yyyy-mm-dd)

Updates between  . . . __________ and __________     (ddmmmyyyy or yyyy-mm-dd)

PTF or ZAP id  . . . . ________

Select Scan results .  /  ScanIns    /  ScanStr    /  ScanSVC
```

Figure 411. Audit Libraries selection menu

This panel, which is common to Audit Libraries menu options **1** to **9**, allows you to specify *selection* criteria. Specify one or more criteria, then press Enter to open the next panel. Libraries and members are selected if they fit *all* of the criteria specified on the Libraries Selection panel.

The **Dsname**, **Member name**, **Disk volser**, and **PTF or ZAP id** fields each accept more than one search string. Each search string can contain generic characters (**%**, * and **) to search for a pattern. To search for an exact string containing these generic characters, enclose the string in single or double quotes. Searching for a substring can be done by prefixing the search string with a colon (**:**).

The **Status at date** and **Updates between** fields accept a date value in either ISO or European date format. The ISO format is `YYYY-MM-DD`, `1999-10-25` for example. The European format is `DDMMYYYY`, `25Oct1999` for example.

Table 253 provides the field descriptions for the Library selection panel.

Table 253. Library selection panel - field descriptions

Field	Description
Dsname	Fully qualified data set name, or a pattern.
Member	Member name. Library reports only include libraries for which at least one member matches the name specified; member reports only include members matching the name specified.
Disk volser	Volume serial number. You should take care with this option when reporting on SMS-managed data sets, as these data sets can change their volume serial over time.
Signature status	Indicates whether a module has the signed attribute set and whether signature verification for the module failed. If the module is signed, select **Program signed**. If the module failed signature verification, select **Verification failed**.
Status at date	For each member, select the version at this particular date. If the date falls in between two freeze dates, and the member has changed in the interim period, the version immediately following the date specified is selected.
Updates between	Select only those data sets that have changed during the period of time specified.
PTF or ZAP id	Select members that contain the particular PTF or ZAP id specified. (For a library report: select only libraries with one or more members containing the PTF or ZAP id.)
ScanIns	Select members in which any of the following instructions were found: BypassSAF, FakeAPF, FakeOper, FakePriv, FakeSpec, KeyzeroRB or ModeSupRB. It is only available if the CKFREEZE file used was produced with parameters `SCAN=YES` and `CHECK=Y` or `CHECKDSN=Y` specified. This field is only present when Status or Scan has been selected.
ScanStr	Select members in which a user specified string was found. It is only available if the CKFREEZE used was produced with parameters `SCAN=YES`, `CHECK=Y` or `CHECKDSN=Y` and `SCANSTR` arguments specified. This field is only present when Status or Scan has been selected.
ScanSVC	Select members in which a user specified SVC call was found. It is only available if the CKFREEZE used was produced with parameters `SCAN=YES`, `CHECK=Y` or `CHECKDSN=Y` and a `SCANSVC` list specified. This field is only present when either the Status or Scan field has been selected.

After pressing Enter on the selection panel, the *exclude* panel in Figure 412 on page 537 is displayed.

```
                    zSecure Audit - Audit - Libraries Exclusion
Command ===> ____________________________________________________________

Exclude libraries and members that fit all of the following criteria:

Dsname . . . . . . . . ____________________________________________ (EGN mask)
Member name  . . . . . ________
Disk volser  . . . . . ______

Updates between  . . . __________ and __________     (ddmmmyyyy or yyyy-mm-dd)
```

Figure 412. Audit Libraries exclusion menu

This panel allows you to specify *exclusion* criteria. Libraries and members selected by the criteria from the previous panel are excluded if libraries or members fit *any* of the criteria specified on this panel. The exclusion criteria are specified in the same way as the selection criteria on the previous panel.

The panel in Figure 413 is the report parameters panel. It is common to all Audit Libraries menus and is the last panel before processing is started.

```
                    zSecure Audit - Audit - Libraries Options
Command ===> ____________________________________________________________

Select options for Library update report:

Show output in DISPLAY or LIST format  . .  DISPLAY__    (Display/List)

Run query in Foreground or Background  . .  FORE_____    (Fore/Back)

Level of detail in reports . . . . . .  DETAILED_    (Concise/Detailed)
```

Figure 413. Audit Libraries report parameters panel

This panel allows you to specify the following processing parameters:

Show output in DISPLAY or LIST format
This option determines whether the data selected is shown in an interactive display (DISPLAY, when running interactive) or in a printable report format (LIST). When memory is tight, or if the output is to be printed, the concise format is preferable. When a small amount of data is selected that must be studied in detail, select the DISPLAY and DETAILED options.

Run query in Foreground or Background
This option determines whether Audit Libraries processing is to proceed in the foreground, or whether to submit a background (batch) job.

Level of detail in reports
This option determines the level of detail in the reports generated. The only report affected at this time is the DUPLICATES report.

If foreground processing is selected, Security zSecure starts processing after Enter is pressed on the processing options panel. During processing, the number of CKFREEZE records read is displayed. After processing, the resulting output is displayed. Processing can be halted by pressing the ATTN key.

If background processing is selected, the usual SUBMIT panel is displayed, allowing you to browse or edit the JCL generated, and then submit a batch job.

Audit Libraries reports

This section describes the reports available using Audit Libraries menu options **1** to **9**. No selection, exclude, or processing option displays are shown; see the previous section for an explanation of those displays.

Option **1** LIB ALL shows an overview of all libraries and sequential data sets described in the CKFREEZE files used, which match the selection and exclude criteria specified. The report shows the data sets selected for each data set with an indication of its type, the number of members found (1' is shown for sequential data sets), the number of changed members or changes to sequential data sets, and the number of members added and deleted. The changed, added, or deleted members are listed as detail information, but no further information for the members is included. A sample batch report is included in Figure 414.

```
Overview of library status

Dataset                                   DS  Memb Member    Chgs  Adds  Dels
SYS1.CICS9103.CICSLPA                     PO     2              2     0     0
                                                   DFHIRP       1     0     0
                                                   DFHPXR       1     0     0
SYS1.VSF2COMP                             PO     4              2     0     0
                                                   FORTVS2      1     0     0
                                                   ILX0TRCE     1     0     0
```

Figure 414. Batch LIB ALL Report

Note that data set SYS1.VSF2COMP has 4 members, but only 2 were changed; the unchanged members are not listed.

Option **2** LIB CHANGES is equivalent to option **1**, but only shows data sets with changes. The reports generated by options **1** and **2** have the same layout.

Option **3** STATUS shows the status of selected members and sequential data sets. It includes detail information for each member, and requires more memory than the previous reports; you are advised to specify strict selection criteria. The resulting reports are split into load-libraries, non-load-libraries, and sequential data sets; each report includes data set names, and, where applicable, the selected member names and detail information for each member. If a member was changed, multiple versions can be included in the report. The DISPLAY version of the report is shown in Figure 415, starting with the data set overview display.

Figure 417. Library Status detail member display

Option **4 CHANGES** is equivalent to option **3 STATUS**, but includes only the *changed* members matching the selection criteria specified. The Status and Changes reports have a similar layout, but the Changes report includes the earliest and latest linkage-edit dates found.

Option **5 SCAN** reports on members with instruction scan or string scan results. The resulting report has the same layout as the Status report.

Option **6 DUPLICATES** reports on duplicate load modules, which can reside in different data sets and can have different names. Additionally, you can use this option to check whether two sequential data sets are identical, assuming that the checksum data for both data sets is present in the `CKFREEZE` file. When you run the Duplicates report, use only one `CKFREEZE` file for the input data source. A sample batch report is included in Figure 418 on page 540.

Figure 418. Batch DUPLICATES Report

The report displays members with identical content (but maybe different names) sorted on member name; for each duplicate, the member names, data set names, PTF, and ZAP ids are included. This option allows you to find duplicates of e.g. AMASPZAP and IEFBR14.

Option **7** APPLICATION is used to summarize the members selected by (guessed) application, based on the member name prefix. A sample batch report is included in Figure 419 on page 541.

```

Figure 419. Batch APPLICATION Report

The report is sorted by application name; for each application, the data sets, and members are included. If Security zSecure is not able to derive the application name, the member is suppressed. See the PREFIX report (option **8**) for an alternative.

Option **8** PREFIX is used to summarize the members by their prefix, which often indicates the product id. A sample batch report is included in Figure 420 on page 542.

```

Figure 420. Batch PREFIX Report

The report is sorted by prefix name; for each prefix, the application, data sets, and members are included. The main difference with option **7** APPLICATION is that those products for which Security zSecure does not derive an application are included.

Option **9** PTF - ZAP is used to summarize the members selected by PTF or ZAP id application. The resulting report is split into a report summarizing PTF ids and a report summarizing ZAP ids. The report does not contain detailed information for the members. A sample batch report summarizing PTF ids is included in Figure 421.

```

```

Figure 421. Batch PTF - ZAP Report

The report is sorted by PTF id; for each id found, the report includes the data set names, the members in each data set that contain the ZAP or PTF, and the linkage-edit date of the load module.

Predefined CARLa scripts

In this section, the sample reports available in the SCKRCARL library are discussed. The convention used to name CARLa scripts is explained in "Naming convention" on page 706

Batch reports

The following batch library audit reports are available. (These start with CKALM.)

Report	Meaning
CKALMAPP	Applications in libraries based on membername prefix (cf. **AU.L.7**)
CKALMCHG	Details of libraries with member level changes (cf. **AU.L.4**)
CKALMDET	Details of libraries with member level information (cf. **AU.L.3**)
CKALMDUP	Identical members in libraries (cf. **AU.L.6**)
CKALMID	Identify ZAPs and identify data in libraries (cf. **AU.L.9**)
CKALMOV	Overview of library status (cf. **AU.L.1**)
CKALMOVC	Overview of library changes (cf. **AU.L.2**)
CKALMPRF	Applications in libraries by component code (cf. **AU.L.8**)

AU.L.5 is not represented separately. Essentially it is the same as **AU.L.3** with a different selection. These reports are a functionally stabilized set of sample CARLa scripts. These samples are not directly used in the interface; use the COMMANDS file on the RESULTS panel after a query to verify the exact CARLa used.

These samples refer to the NEWLIST NAME=LIBSEL statement with a LIKELIST=LIBSEL clause. Make sure that either a NEWLIST with that name and the appropriate selections is included in the query ahead of them, or specify SUPPRESS MSG=403. See also "Selecting based on previously specified criteria (LIKELIST)" on page 887 and "Using record display scripts for interactive reporting" on page 591.

Chapter 7. SMF and HTTP Reporting (Events menu)

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

zSecure provides record processing and reporting for the following types of SMF and HTTP data:

- live SMF data sets
- SMF log streams
- sequential SMF data that has been produced by the `IBM IFASMFDP` or `IFASMFDL` programs
- HTTP access, error, or site-defined log files

This data can be useful for monitoring user activity and MVS events.

For details on SMF processing, select one of the following topics:

- "Selecting and dumping SMF data sets"
- "Using Security zSecure to process SMF data instead of IFASMFDFP" on page 549
- "Interactive SMF processing for RACF" on page 550
- "Batch SMF processing" on page 589
- "SMF reporting using predefined CARLa scripts" on page 590

Selecting and dumping SMF data sets

You select the SMF data source for reporting from the SETUP options available from the Main menu. (**SE.1**). The data source is defined by an input set which can include one or more files containing the data for reporting. You can either create an input set for the SMF data sources or add them to an existing input set. You can use any of the following types of data sets or files for the SMF input:

- Live SMF data
- Fully qualified data set names, or relative GDG generations
- SMF log streams
- A GDG base name to allocate all generations of a GDG

When you specify the data set or file information, you must ndicate the data type. Table 254 lists the supported data types for SMF input sources.

Table 254. Data set types for SMF input data sources

SMF data	Input set TYPE value	Example
VSAM data sets or dumped non-VSAM data sets	SMF	See "Specifying a dumped SMF data set or a live SMF data set from another system" on page 547.
Live SMF	ACT.SMF	See "Specifying a live SMF file" on page 546.
SMF log streams	SMF.LOGSTR	See "Specifying SMF log stream input data" on page 548.

Table 254. Data set types for SMF input data sources (continued)

SMF data	Input set TYPE value	Example
SMF data sets on tape	SMF	See "Specifying SMF data sets on tape" on page 548.

You can use Security zSecure to unload live data sets and also any local unloaded SMF data available online. See "Using Security zSecure to process SMF data instead of IFASMFDFP" on page 549. For information about which record types to use, see "Adding SMF data sources to input file sets." If you have any local unloaded SMF data available online, you can also read this data set using Security zSecure.

Adding SMF data sources to input file sets

Use the Setup Input Files menu option to add the SMF input data sets or files and select them for processing.

To use this function, select the Setup Input Files menu option available from the Main menu (SE.1) or type SETUP FILES on the command line. When you select this option, the Setup - Input files panel shown in Figure 422 opens.

```
 Menu   Options   Info   Commands   Setup

****************************** BOTTOM OF DATA ********************************
```

Figure 422. Setup Input files

The Setup - Input files panel shows a list of the input sets that are currently defined.

From this panel, you can do the following:

- Use the **I** line command to add a new input set.
- Use the **E** line command to edit an existing input set.

For more information, see "SE.1 Setup - Input files" on page 1645 and the *IBM Security zSecure Admin and Audit for RACF: Getting Started Guide* Guide.

Specifying a live SMF file

To specify a live SMF file, do the following:

1. Follow the procedure to add a data source "Adding SMF data sources to input file sets."
2. When you get to the step to specify the information for the live SMF file, type `ACT.SMF` in the **Type** column as shown in Figure 423 on page 547.

Specifying a data set name for a live SMF data source is optional. READ access to the SMF recording data sets is required.

```

Figure 423. Specifying a live SMF file

Specifying a dumped SMF data set or a live SMF data set from another system

To specify a dumped SMF data set or a live SMF data set from another system, do the following:

1. Follow the procedure to add a data source "Adding SMF data sources to input file sets" on page 546.
2. When you get to the step to specify the information for the live SMF file, type SMF in the **Type** column.
3. Type the enter the fully qualified data set name as shown in Figure 424.

You can also use the DSNPREF= option to specify a collection of SMF input data sets that begin with a specified high-level qualifier. For example, specifying DSNPREF=SYS1.DAILY.SMF specifies all data sets that begin with *SYS1.DAILY.SMF*. The last qualifier specified is interpreted as a partial qualifier. To match only full qualifiers end the DSNPREF value with a period.

Figure 424. Specifying a dumped SMF file

Specifying SMF log stream input data

To specify a dumped SMF data set or a live SMF data set from another system, do the following:

1. Follow the procedure to add a data source "Adding SMF data sources to input file sets" on page 546.
2. When you get to the step to specify the information for the file, type `SMF.LOGSTR` in the **Type** column.
3. Then, type the data set name as `logstream_name('time','SID(sysid)')`, where `time` and `sysid` are optional.

   The following examples show valid specifications for the data set name.

   - `IFASMF.TYPE80` or
   - `IFASMF.TYPE80('DURATION=(24,HOURS)')` or
   - `IFASMF.TYPE80('FROM=(2007/288),TO=(2007/288),LOCAL','SID(IPO1)')`

Specifying SMF data sets on tape

You can also specify multiple SMF data sets and GDG names for SMF reporting.

1. Follow the procedure to add a data source "Adding SMF data sources to input file sets" on page 546.
2. Type `SMF` in the **Type** column.Figure 425 illustrates how you specify multiple SMF data sets and GDG names.

```

****************************** Bottom of data ********************************
```

Figure 425. Specifying SMF files using GDG names

3. After you enter the data set or tape names, type SAVE on the command line to save the input set.

To use this input set for reporting, submit a batch job using the **CO** option available on the main menu. For details, see "Batch SMF processing" on page 589. If you have MOUNT authority, you can use this input set for interactive reporting but we do not recommend it.

Selecting HTTP and user-defined logs

You can create reports for HTTP and user-defined logs by selecting an HTTP or user-defined log file as an input source. You can generate reports on the following log types:

- WEBACCESS for HTTP access logs

- WEBERROR for HTTP error logs
- Site-defined log types (See “SE.U SETUP - user-defined input sources” on page 1667.)

SMF log files can also be read directly from a UNIX file system.

1. Add a data source. (See “Adding SMF data sources to input file sets” on page 546).
2. In the **Type** field, type one of the input file types for HTTP logs. To read files directly from UNIX, specify the full path name under **Data set** or **Unix** file name.

Figure 426 shows an example that adds two HTTP log data sources to an input set.

Figure 426. Specifying HTTP logs

Using Security zSecure to process SMF data instead of IFASMFDFP

You can use the RACF SMF data unload utility IFASMFDP to read any VSAM or non-VSAM SMF data set and write selected records to a sequential file. You can process the sequential file using Security zSecure. However, you can also read SMF data (both live and unloaded) directly with zSecure instead of using IFASMFDP. For example, the zSecure job C2RJFUNL reads live SMF, selects and then rewrites specific record types. The resulting data set can be blocked efficiently and contains fewer records than the IFASMFDP output file. You can improve processing speed by using the zSecure data set as the data source.

You can also customize the selection of SMF records in the C2RJFUNL job. For example, the SMF record types that DFSMShsm writes are customizable. If you want to include DFSMShsm daily statistics or functional statistics records in your selection, add the SMF record type for DFSMShsm in job C2RJFUNL. The record type number for the statistics records is one more than the value specified in the SETSYS SMF command in DFSMShsm's configuration.

Interactive SMF processing for RACF

The SMF processing application is available from the Events options (**EV**) on the main menu. Use these options to specify the audit selection criteria for creating reports on the SMF record types, user or group event records for example. Depending on the options you specify, the data can be processed in the foreground on the ISPF panels or you can submit an equivalent batch job. The report results are sent to the ISPF display or a printed report depending on the options specified in the selection panels.

Figure 427 shows the main menu for Events.

Figure 427. EVENTS main menu

Table 255 lists the Events menu options and descriptions.

Table 255. Events menu options and descriptions

Event Function	Description
U User	Select and list SMF records concerning specific users. See “Reporting on user events (EV.U)” on page 564.
G GROUP	Select and list SMF records concerning specific groups. See “Reporting on group events (EV.G)” on page 565.
D Data set	Select and list SMF records concerning specific data sets. See “Reporting on data set events (EV.D)” on page 566.
R Resource	Select and list SMF records concerning specific resources. See “Reporting on general resource events (EV.R)” on page 567.
F Filesystem	Select and list log records (SMF and other) concerning USS files. See “Reporting on Unix file system events from SMF and other logs (EV.F)” on page 568.

Table 255. Events menu options and descriptions (continued)

Event Function	Description
I IP	Select and list log records (SMF and other) concerning IP addresses and connectivity statistics. See “Reporting on IP events from SMF and other logs (EV.I)” on page 569.
1 SMF reports	Run predefined analysis reports. See “Logging for specific RACF events (EV.2 - RACF EVENTS)” on page 578.
2 RACF events	Select and list RACF processing records to trace specific event types, such as access violations or use of RACF commands. See “Logging for specific RACF events (EV.2 - RACF EVENTS)” on page 578.
4 DB2	Select and list SMF records concerning DB2. See “Reporting on DB2 EVENTS (EV.4)” on page 570.
5 CICS	Select and list SMF records concerning CICS monitoring information. See “Reporting on CICS monitoring events (EV.5)” on page 571.
6 Omegamon	Select and list SMF records for Omegamon events. See “Reporting on Omegamon events (EV.6)” on page 572.
C Custom	Specify custom queries that do not fit the standard criteria of the other options. Use this option to create custom report displays and to create summaries. You can also use the predefined report layouts that are used by the other menu options. See “Creating custom queries and reports (EV.C CUSTOM)” on page 586.

For additional information about the Event menu options, use the F1 function for help on a field or panel.

Querying SMF data

The following procedure provides instructions for querying SMF data for information about user, group, data set, general resource, Unix filesystem, IP, DB2 and CICS monitoring.

1. Select the Events menu option for the information type you are interested in. For example, if you want to investigate user events, type **EV.U** on the command line.
2. On the selection panel, enter the base selection criteria for the query as described in Table 256.

Table 256. Specifying selection criteria for SMF records

To select ...	Do this ...
Select all SMF records that have information related to the specified event (user, group, DB2, CICS monitoring, for example)	Leave the fields on the record selection panel blank, then press **Enter** to show the records.
Select SMF records based on user-specified search criteria	Select one or more fields on the record selection panel. Then, press **Enter** to show the list of records matching the selection criteria.
Select SMF records using search filters.	In some selection fields, you can enter a filter. For example, on the User Events - Record panel, you can select all records that relate to actions performed by users that have the characters C##QAO in the first 6 positions by typing `C##QAO*` in the user ID field.

3. Optionally, you can specify advanced selection criteria to further qualify the SMF record selection.
   - Type / in the input field for each advanced selection criteria option you want to use.
   - At the prompt, specify the criteria for each of the advanced options you selected on the report selection panel. For details, see "Specifying advanced selection criteria for SMF records."
4. Specify the Output/Run options.

   Use the **Output/run** options for configuring any of the Event selection panels. The selections you specify are saved to your ISPF profile and become the default setting for all the selection panels. As a result, you can set an option one time (**Output in print format**, for example) and use it for all SMF event reporting. For details on these options, see "Selecting Output/run options" on page 562.
5. After you specify the selection criteria and output and run options, press **Enter** to process the query.

   If you have selected any of the advanced selection criteria options, a series of panels opens so you can specify the selection criteria details. After you finish using these panels, you might also be prompted to provide additional information about the output and run option settings.
6. After you submit the job, the query results are sent to either an ISPF display panel or a printed report, depending on the output and run options you selected.

   For online results, you can use line commands to review the results. See "Using line commands on SMF data report result panels" on page 563.

Specifying advanced selection criteria for SMF records

You can further qualify the selection criteria for SMF records using the Advanced selection criteria options available on the Events selection panels. The advanced options available depend on the type of report you are generating. When you select multiple options, the panels for specifying the criteria are presented in sequence before the query is processed.

1. Type / in the input field for the advanced selection criteria you want to specify.
2. Press **Enter**.
3. For each advanced criteria option you selected, use the panels that open to specify the criteria.
4. Press **Enter** to process the query.

Figure 428 on page 553 shows the advanced selection criteria options available for User Event reporting. Table 257 on page 553 describes the advanced selection criteria available for SMF records.

Selecting Output/run options

Use the **Output/run options** to control how your query is run and the format of the generated output.

The **Output/run options** settings you specify on any of the Events panels are saved in your ISPF profile. They become the default settings for all Event panels that provide the option. For example, if you select the **Output in print format** option that option becomes the default setting on all the other Event panels that include that option. Some options require further configuration before running the query. The program provides configuration panels for these options after you select them.

To specify the output and run options for a query, do the following:

1. To change the default setting on a panel, remove the selection from the field.
2. For each option you require, type a / in the selection field for the option.
3. Press **Enter**.
4. Specify any further configuration for each option on the subsequent panels that open. Only some options require further configuration. The program prompts you for the information when required.

   If you select multiple options, any configuration panels for the options are presented in sequence until all required output and run parameters are specified.
5. Press **Enter** to run the query. (See "Querying SMF data" on page 551.)

Table 258 describes the available output and run options.

Table 258. Output and run options for

Output/Run option	Description
Include detail	Check this option to create a detailed report or display rather than the default one line per event summary display. If you have selected **Output in print format**, the report has between two and four output lines for each event. If an ISPF display is generated, each event has its own detail display. This option cannot be used in combination with the **Summarize** option.

Table 258. Output and run options for (continued)

Output/Run option	Description
Summarize	Check this option to creates a summary report or display with a one line summary of each SMF record. This option cannot be used in combination with the **Include detail** option.
Specify scope	Check this option to limit the output to the scope of a user ID or group, that is only the resources to which the specified user or group has direct or indirect access are reported.
Output in print format	Check this option to generate a printable report. When this option is selected, you can also use the options to customize the report title and send the report using email.
Customize title	Change the default report title. This option is only available when the **Output in print format** option is selected.
Send as email	If **Output in print format** is selected, you can select this option to send the report using email. A panel opens for specifying the email address destination for the report. The email function does not work until you have configured the SMTP options with `SETUP OUTPUT`. See "SE.7 Setup - Output" on page 1665.

Using line commands on SMF data report result panels

On the results panel for SMF queries, you can use line commands on the overview and detail display. Commands can be generated by issuing a line command at the start of a line. Line commands on both the overview and detail displays depend on the type of field that is shown.

Line commands on overview displays: Table 259 list the commands available for SMF records containing RACF data set profile information. Some of these actions might not be available to you because of the installed product combination, system specifications, or authorization.

When you use the / line command to verify which line commands are permitted, the following table is shown.

Table 259. Line commands on overview displays - RACF data set profiles

Command	Meaning	Explanation
C	Copy data set profile	C - Copy "Line commands" on page 54
D	Delete data set profile	D - Delete "Line commands" on page 54
L	List profile	The output of the `listdsd` command is presented in a browse panel.
P	Display data set profile	"Dataset profile detail display" on page 140
S	Show additional information	S - Select "Line commands" on page 54

Line commands on detail displays: Line commands on detail displays depend on the type of field that is shown. Table 260 on page 564 shows a list of the available commands. To include the detail information in the output, select the **Include**

detail option from the **Output/Run options** field group on the selection panels. See "Selecting Output/run options" on page 562.

Table 260. Line commands available on detail displays

Command	Meaning	Explanation
B	Browse data set	Only available for the data set field. This command browses the selected data set using the ISPF BROWSE service.
L	List profile	Only available for fields containing RACF profile information, user ID for example. The output of the list command is presented in a browse panel.
N	NSLOOKUP	Only available for TCP/IP and Firewall fields containing IP address information. The NSLOOKUP command queries a domain name server for information about a host or domain. This command can be interrupted with ATTN.
P	PING	Only available for TCP/IP and Firewall fields containing IP address information. The PING command sends an echo request to a node to determine whether the computer is accessible. When a response is received, the elapsed time is shown. Otherwise, a timeout message shows after a few seconds. This command can be interrupted with ATTN.
T	TRACERTE	Only available for TCP/IP and Firewall fields containing IP address information. The TRACERTE command sends UDP requests with varying TTL (time-to-live) values and then waits for the routers between the local and remote hosts to send TTL-exceeded messages. This command can be interrupted with ATTN.

Reporting on user events (EV.U)

The User Events panels are designed to select and show SMF audit trail records related to actions performed by users. SMF records that do not relate to something that was performed under the authority of a user ID are not selected. For example, records related to system events such as an IPL are not selected, but the commands issued by a user might be.

To specify selection criteria and generate the report, type **EV.U** on the command line to open the selection panel shown in Figure 444 on page 565.

```

Reporting on Omegamon events (EV.6)

The Omegamon Events panels are designed to select SMF audit trail records related to Omegamon commands. If the SMF record does not relate to an Omegamon command, it is not selected. For example, records related to system events such as an IPL or MVS commands issued by a user are not selected.

To specify selection criteria and generate the report, type **EV.6** on the command line to open the selection panel shown in Figure 452 on page 573.

```

1    Exceptions      RACF exception report
2    Stat hour       RACF statistics by hour (very wide report)
3    Stat time       RACF statistics by time
4    Stat day        RACF statistics by weekday
5    Revoke/resume   RACF revoke/resume summary
9    Job viols       Dataset violations by batch jobs
A    APPC conv       APPC conversation summary
```

Figure 453. Events SMF reports menu

Table 261 describes the available report options.

Table 261. Predefined SMF Analysis report options

1 Exceptions	Create a group of reports showing all RACF exceptions; both DETAIL and LIST formats are supported. The layout of each report type is dependent on the RACF event type described. No select or exclude parameters can be specified with this report.
2 Stat hour	Show RACF: statistics by hour, in a wide layout (180 positions).
3 Stat time	Show RACF statistics by hour, in a layout fitting into 80 positions.
4 Stat day	Show RACF statistics by weekday, in a layout fitting into 80 positions. Use this option with SMF data for several days. If you use live SMF data, the report only includes all events that occrred on one day (today).
5 Revoke/Resume	Show RACF revoke and resume command activity summarized in two ways: by target user ID and by administrator.
9 Job viols	Show batch jobs and started tasks that have data set security violations.
A APPC conv	Show APPC conversations summarized in 4 ways: by local LU name, by partner LU name, by local RACF group, and by local user ID and descending frequency.

For most report types, after you select the report option, a series of panels are shown so you can specify additional select, exclude, and report parameter panels. These panels are described in "Generating pre-defined SMF and RACF event reports" on page 579.

For more information on reports and report examples, see the following topics:

- "RACF Exceptions report example"
- "RACF statistics report example" on page 576

RACF Exceptions report example

The RACF Exceptions report provides a list of all RACF exceptions logged. This example starts with the RACF Exceptions report overview which organizes RACF events into different report types. The overview is followed by samples of the detail information you can access from the overview panel.

After you run an **Exceptions** report, a selection panel shows the RACF events ordered into different report types. The report overview panel shown in Figure 454 on page 575 opens.

Figure 457. RACF statistics by time of day

The **Dsc** and **SAF Auth** columns in this report describe the RACF descriptor and RACF authority used. Table 262 shows the descriptor values that can occur.

Table 262. RACF Descriptor values

Descriptor value	Meaning
S	Success
U	Undefined user
V	Violation
W	Warning

Table 263shows the RACF authority values that can occur.

Table 263. RACF authority values

SAF auth value	Meaning
A	Auditor
B	Bypasses-user id = *BYPASS*
F	Failsoft processing
N	Normal authority check
O	OPERATIONS attribute
S	SPECIAL attribute

Table 263. RACF authority values (continued)

SAF auth value	Meaning
Su	OpenEdition MVS superuser
Sy	OpenEdition MVS system function
T	Trusted/Privileged attribute
X	Installation exit processing

For details, see "SMF: SMF records" on page 1276.

Logging for specific RACF events (EV.2 - RACF EVENTS)

Use the menu option **2** RACF EVENTS to audit specific RACF event types. When you select this option, the panel shown in Figure 458 opens.

```
  Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - Events - RACF events
Command ===> ____________________________________________________________

Enter "/" to select report(s)
_  All events       Overview of all following RACF events (except IPL)
_  Logging          RACF logging of all events except RACINIT
_  Not normal       RACF access not due to normal profile access
_  Warnings         RACF access due to profiles in warning modes
_  Violations       RACF access violations
_  Commands         RACF command auditing
_  CKGRACF          zSecure Admin CKGRACF commands
_  IPL RACF         RACF initialization
```

Figure 458. RACF EVENTS panel

Table 264 describes the available RACF Event report options.

Table 264. Events menu - RACF Event report options

All events	Select all RACF processing records and summarize them by event and event qualifier. Use this option to view all records for any distinct event, all invalid new password attempts for example. This option is mutually exclusive with all other, more selective, options. It also requires the largest amount of CPU time and memory.
Logging	Select all logged RACF processing records except RACINIT records. The resulting report includes command usage, access checks, and class and user logging. Job starts and logon events are not included.
Not normal	Select all RACF processing records where an authority other than normal was used. (Normal is the default for most users.) The selected authority types are: Operations, Special, Exit, Auditor, Failsoft, Bypassed, and Trusted.
Warnings	Select all accesses due to profiles in warning mode. These accesses were permitted but caused a warning to be issued. Other warning events are not selected.
Violations	Select all access failures. Other violations (like failed logons) are not selected.
Commands	Select all logged commands. This option selects all SETROPTS and RVARY commands, all commands requiring AUDITOR authority, all commands requiring special authority (only if SETROPTS SAUDIT is in effect), all ADDSD and RDEFINE commands requiring operations authority (only if SETROPTS OPERAUDIT is in effect), all commands issued by audited users (due to ALTUSER UAUDIT), and all command violations (only if SETROPTS CMDVIOL is in effect).

Table 264. Events menu - RACF Event report options (continued)

CKGRACF	Select all records written by the CKGRACF authorized component of Tivoli zSecure Manager for RACF z/VM. Both EVENT=ACCESS and EVENT=GENERAL records are selected. For more information about CKGRACF and the SMF records it writes, see Chapter 14, "CKGRACF Command Language," on page 1499.
IPL RACF	Select all records written at start of RACF (during IPL processing). These records contains the SETROPTS settings in use.

After selecting the report types on this panel, the selection, exclusion, and processing options panels are shown so you can specify further selection criteria. Records that meet the any of the following conditions are selected:

- Record is selected only if it matches one of the selected RACF event types.
- Matches the additional selection criteria.
- Does not match any of the exclusion criteria.

For information about generating and reviewing the reports, see the following topics:

- "Generating pre-defined SMF and RACF event reports"
- "Reviewing the RACF event reports" on page 582

Generating pre-defined SMF and RACF event reports

The SMF report (**EV.1**) and the RACF events (**EV.2**) functions provide pre-defined report layouts to format the SMF and RACF event data generated from the specified selection and exclusion criteria. The process to set up and generate the SMF and RACF Event reports is similar.

1. Specify selection criteria if prompted.

   For some report types, you cannot specify selection or exclusion criteria because the report type already focuses on a targeted set of data. For these reports, the report processing and display options panel opens immediately so you can limit the processing to a specified number of records, specify whether to include SAF (System Authorization Facility) data, and specify display and output options.
2. Specify exclusion criteria if prompted.
3. Specify report processing, display and format options.
4. Press Enter to begin processing the selected data.
5. SMF processing can be interrupted by pressing the **ATTN** key. No more records are read, but processing continues.

   When you press this key, no more SMF records are read, but report processing continues. The resulting report includes information about the records that were processed before the ATTN key was pressed.
6. Review the report data on the display or in the printed report, depending on the options selected.

Related topics

- "Selecting event data" on page 580
- "Excluding event data" on page 580
- "Setting the report processing and display options" on page 581
- "Reviewing the RACF event reports" on page 582

Selecting event data

Use the Event selection panel to specify *selection* criteria to filter the report data. For each criteria you want to use, type a / , option number, or input value in the entry field, then press Enter for the next panel. Records are selected if the records fit *all* of the criteria specified on the panel.

After you enter the selection criteria, the Event exclusion panel opens so you can filter the selected records further.

```
 Menu   Options   Info   Commands   Setup
------------------------------------------------------------------------------
                        zSecure Suite - Events - SMF selection
Command ===> ____________________________________________________________

Select SMF records that fit all of the following criteria
Use EGN masks for selection criteria
Userid  . . . . . ____________________________________________________________
Jobname . . . . . ____________________________________________________________

Show all            _  Success   _  Warning   _  Violation
```

Figure 459. EVENTS selection menu

For detailed field descriptions, press F1 on the ISPF panel to view the help. The options selected on this panel are written to your ISPF profile and stored as the default values for the selection panel. If you change a selection, the default values are updated.

Excluding event data

After specifying selection criteria, the Event exclusion panel is open, so you can specify *exclusion* criteria. Records selected by the criteria specified on the preceding Event selection panel are excluded from the report if the records fit *any* of the criteria specified on this panel. The exclusion criteria are specified in the same way as the selection criteria. (See Figure 459.)

After pressing **Enter** on the selection panel, the *exclude* panel shown in Figure 460 on page 581 opens.

```
 Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------

 Max number of records per display group  ________   (default is no limit)

 Complete with SAF data  1  1. Yes        2. No      3. Minimal

 _  Output in print format
 _  Use CKFREEZE data
 _  Show number of SMF records selected
 _  Run in background
```

Figure 461. EVENTS report parameters panel

For detailed field descriptions, press F1 on the ISPF panel to view the help. The options selected on this panel are written to your ISPF profile and stored as the default values for the selection panel. If you change a selection, the default values are updated.

After you specify the processing options and press Enter, report processing begins. During processing, data on the number security database record profiles, CKFREEZE records, and SMF records read is tracked. SMF processing can be interrupted by pressing the **ATTN** key. When you press this key, no more SMF records are read, but report data processing continues.

When processing is done, the report data is shown online or written to a report file depending on the options you selected. Written reports are generated through a batch job submitted in the background. Online reports open immediately after processing ends. For examples of the interactive reports, see "Reviewing the RACF event reports."

Reviewing the RACF event reports

RACF event reports can be sent to a printed report or an interactive online display. This topic describes the interactive reports. If you selected a printed report, you can review the report data in the file generated by the batch job that ran the report.

From the interactive RACF Event reports, you can view the following types of information:

- Summary of RACF record report data

  During processing, data on the number security database record profiles, CKFREEZE records, and SMF records read is tracked. If you select the **Show number of SMF records selected** processing option, this summary information can be viewed from the RACF Display Selection panel. (See Figure 462.)
- Summary of RACF event records by event type
- List of selected RACF records
- To view RACF records summarized by RACF event type, use the **All events** report option. From this view, you can drill down to view records by event type and details on individual events.
- The other reporting options output a list of all selected records without any summary information. From this view, you can drill down to view the event details for specific records. (See Figure 466 on page 585.)

Viewing summary of RACF event report data: During processing, data on the number security database record profiles, CKFREEZE records, and SMF records read is tracked. If you select the **Show number of SMF records selected** processing option, this summary information can be viewed from the RACF Display Selection panel shown in Figure 462.)

If you selected the **Show number of SMF records selected** option on the Event options panel (see Figure 461 on page 581), the Display Selection panel shown in Figure 462 is open to access a summary of the selected records. If you did not select that option, the list of selected records is opened on the SMF record RACF processing and audit records panel shown in Figure 464 on page 584.

Figure 463. EVENTS - Selected record summary

RACFDATA

Selecting the RACFDATA option opens the SMF record RACF processing and audit records panel. The information shown depends on what type of RACF event report you selected.

The *All events* reporting option provides a summary of selected records organized by RACF event type as shown inFigure 466 on page 585. The display also lists the numeric event qualifiers for each event type. This summary by RACF event type is only available for the *All events* reporting option.

All events reporting option

This option generates a summary view showing selected RACF event records organized by type as shown in Figure 464 on page 584. The display also lists the numeric event qualifiers for each event type.

Figure 467. RACF event detail display

Creating custom queries and reports (EV.C CUSTOM)

Use the EVENTS menu option C CUSTOM to create custom queries and displays. This customization uses predefined detail layouts to generate queries. You can use this panel to phrase queries that do not fit the selection and exclusion panels provided on other SMF menus. You can also create queries using the COMMAND or LIBRARY options on the main menu.

The following examples show a custom query with a predefined layout followed by a custom query with a custom layout.

The display in Figure 468 on page 587 shows the first CUSTOM panel.

```
  Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                        zSecure Suite - Events - Custom
Command ===> ____________________________________________________________

newlist type  . . . . . SMF_____________________

Enter up to 3 SELECT condition sets (use EGN masks)
Select  user=CRMB*_____________________________________________________________
Select  _______________________________________________________________________
Select  _______________________________________________________________________

Enter up to 3 EXCLUDE condition sets (use EGN masks)
Exclude jobname=ifasmfdp_______________________________________________________
Exclude _______________________________________________________________________
Exclude _______________________________________________________________________

Enter up to 3 DEFINE commands
Define  _______________________________________________________________________
Define  _______________________________________________________________________
Define  _______________________________________________________________________
```

Figure 468. EVENTS CUSTOM query panel

- You can specify any SELECT and EXCLUDE clause on this panel.
- Use AND, OR, and NOT to combine clauses.
- Valid NEWLIST types are SMF and all DEFTYPEs defined in SE.U (see "SE.U SETUP - user-defined input sources" on page 1667).
- All the fields defined for the `NEWLIST` specified can be used (for `NEWLIST TYPE=SMF` see "SMF: SMF records" on page 1276 for a language reference).
- To be selected, a record must match any SELECT statement and none of the EXCLUDE statements. If no SELECT clause is specified, all records are selected (before EXCLUDE processing); if no EXCLUDE clause is specified, no records are excluded.
- You can also define boolean or statistic variables for a custom display. These variables or other user-defined fields cannot be used in the predefined layouts.

The selection panel is followed by the custom display panel in Figure 469 on page 588.

```
  Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                        zSecure Suite - Events - Custom
Command ===> ____________________________________________________________________

Enter output variables:
Display ____________________________________________________________________
        ____________________________________________________________________
        ____________________________________________________________________

Enter summary variables:
Summary ____________________________________________________________________
        ____________________________________________________________________
        ____________________________________________________________________

Or select one or more default reports:
_ RACF processing and audit                    _  CICS audit
s  Job activity                                 _  DB2 audit
s  Dataset activity                             _  Firewall activity
_  ICF catalog                                  _  Unix filesystem activity
_  VSAM catalog                                 _  IP connection activity
_  Basic report for unsupported records
```

Figure 469. EVENTS CUSTOM display panel

Use this panel to specify a custom display, a custom summary, or both. As an alternative, you can use any of the predefined detail layouts. In the preceding example, the predefined job and data set activity layouts have been selected. All record types not fitting these layouts are skipped. This processing behavior means that you can use the predefined layouts are therefore an additional selection mechanism.

The custom display panel is followed by the processing options menu. Depending on your query, you should make use of the CKFREEZE and completion options. In the example query, the **Complete with SAF data** option should be selected. (Without it, selection of data set activity records by RACF user ID would fail.)

After processing, the usual record overview and detailed display panels are shown. The panel in Figure 470 shows an overview panel with data set activity records.

Batch SMF processing

This manual gives most attention to the Security zSecure ISPF interface. However, Security zSecure can also be used in batch mode. This section describes how to use the batch mode.

Table 265. Batch SMF processing commands and functions

Command or Function	Description
Run in background	Use the Output/Run option available on the Event panels to generate the Event query and submit a batch job to generate the report types selected
CO Commands	Use this Security zSecure main menu option to submit custom queries or queries from CARLa libraries. The SCKRCARL data set provides sample batch reports that can be used as is, or customized based on your reporting requirements.
Custom JCL	To create your own JCL to submit the Security zSecure batch job, start with the JCL samples in the SCKRCARL data set, or the JCL generated by Security zSecure when you submit a background job.
Create custom reports	In your own JCL, you can use the INCLUDE command to imbed CARLa scripts from the SCKRCARL data set or your own libraries. You can also use the full Security zSecure language (CARLa) to create your own custom reports. When you create your own queries, read the SMF language reference at least once. See "SMF reporting using predefined CARLa scripts" on page 590 for an overview of the sample reports included with Security zSecure. We advise you to read, then try the SMF batch reports CKALF... at least once.

Tip: When submitting a batch job from the Security zSecure ISPF application, you can specify tape data sets using option **5** SELECT on the SUBMIT panel. This allows you to read SMF data sets from tape without MOUNT authority.

SMF reporting using predefined CARLa scripts

Security zSecure provides sample reports in the SCKRCARL library. These reports are created from scripts written in the CARLa programming language. The convention used to name CARLa scripts is explained in "Naming convention" on page 706.

You can run these sample scripts directly or access the functionality from the IBM Security zSecure user interface. You can also modify the existing scripts to develop your own custom reports using the standard display formats provided in the sample files.

For details on these scripts, see the following sections.

- "Field definitions for SMF and other log files"
- "Using record display scripts for interactive reporting" on page 591
- "Batch reports" on page 592

Field definitions for SMF and other log files

The CARLa Auditing and Reporting Language (CARLa) allows you to define variables for parts of SMF records, and then use them in reporting. You can also define the layouts of other logs using the DEFTYPE command. Table 266 lists the CARLa scripts that include such definitions (CKAS*), Many of these scripts are used for the reports in the following sections.

Table 266. CARLa scripts that define variables for fields in SMF records

Member	Definitions
CKASKERB	Kerberos fields (in RACF relocate sections 331 through 335)
CKASSECP	SecurPass fields
CKASUSS	z/OS Unix System Services fields (in RACF records)
CKASWBAC	HTTP access log (DEFTYPE TYPE=WEBACCESS)
CKASWBER	HTTP error log (DEFTYPE TYPE=WEBERROR)
CKAS0119	SMF record type 119 subtypes 48-52 (CSSMTP client)
CKAS0033	SMF record type 33 (APPC Transaction Record)
CKAS0080	SMF record type 80/83 (RACF and R_auditx records)
CKAS0081	SMF record type 81 (RACF initialization)
CKAS0089	SMF record type 89 (Usage data)
CKAS0090	SMF record type 90 (System status)
CKAS0092	SMF record type 92 (z/OS UNIX System Services)
CKAS0102	SMF record type 102 (DB/2)

Using record display scripts for interactive reporting

The SMF record display scripts which start with the name pattern C%ADF are used by the interactive component of Security zSecure to generate SMF data reports for the ISPF display. Many of these scripts cannot be run directly as a library member.

These CARLa scripts typically define a display for a specific group of SMF records such as ICF catalog records. If you follow the conventions used by Security zSecure, you can include these display layouts in your own queries.

To follow the convention for creating an SMF report, use the following process:

- Create a SMF NEWLIST with the name SMFSEL and output limit 0.
- Use SELECT and EXCLUDE statements to select the records you are interested in.
- Include a fake LIST, SORTLIST, or DISPLAY command.
- Then include any SMF sample member. The CARLa scripts select the records fitting their layout from the selection of the NEWLIST named SMFSEL, and using the appropriate DISPLAY commands to show all relevant data from those records types.

The following sample query shows the Security zSecure convention for coding report data. The query selects records from users `JOHN`, `DAVE`, and `PETER`, and then includes the CARLa scripts defining data set and `ICF` catalog activity.

```
newlist type=smf name=smfsel outlim=0      /* Required newlist */
select user=(john dave peter)              /* Selection */
list type                                  /* Fake list command */
i m=ckadfdda                               /* Data set activity */
i m=ckadfdic                               /* ICF Catalog */
```

Table 267 describes the SMF record display scripts. You can access these record display from the menu structure.

Table 267. IBM Security zSecure SMF record display scripts

Member	SMF record types
CKADFDAR	RACINIT record layout from SMF type 30
CKADFDDA	Data set activity
CKADFDFS	z/OS UNIX file activity
CKADFDIC	ICF catalog activity
CKADFDJA	Job activity
CKADFDOT	Miscellaneous 'other' records
CKADFDRA	RACF processing records (defines various display layouts, depending on event type)
CKADFDRS	RACF processing records (one display layout, can be used with a SUMMARY)
CKADFDVS	VSAM catalog activity
CKADFDZZ	Common SMF header display
CKADFD02	DB/2 record types 100, 101, and 102
CKADFD81	RACF status record display in format like CKRDSR80
CKADFD90	MVS event information: defines displays for IPL reason and down time, SRM data, LOGREC, SMF stop and switch events

Table 267. IBM Security zSecure SMF record display scripts (continued)

Member	SMF record types
CKADFJOB	Summary of activity by user and job
CKADFJ33	APPC transaction summaries
CKADFSUM	Summary of record types selected
CKADFTCP	TCPIP activity
CKADF109	Firewall activity

Batch reports

Table 268 describes the reports you can run using a batch process.

Table 268. zSecure Batch reports

Report	Meaning
CKALFDES	Overview of record descriptions
CKALFDEV	Find use of a specific device type
CKALFJES	Show JES2 related logging
CKALFJOB	Overview of job activity for selected users (must be edited before it is used)
CKALFJVI	Jobs with failures
CKALFJ33	APPC transaction overviews (partner LU and local LU overviews, local user ID and group overviews)
CKALFNPR	Find access to data sets without RACF profile. Can be used to find potential PROTECTALL problems
CKALFREV	Generate a REVOKE for users with too many password or password phrase changes (review before using)
CKALFRST	RACF daily statistics of logon and access events, and the number of violations
CKALFRVR	Revoke and resume summaries by user and by administrator
CKALFR80	RACF daily report of violations, special/operations activity, audited users, RACF command use, command violations, and all non-success records
CKALFR81	RACF IPL status records, format compatible with CARLa script CKRLSR13
CKALFSEL	(Dummy) selection NEWLIST SMFSEL
CKALFSTA	RACF event counts by hour
CKALFSTB	RACF event counts by time of day
CKALFSTC	RACF event counts by weekday
CKALFSUM	SMF record summary table
CKALFTAP	Find users of round tapes (can be edited to select other unit types)
CKALFUSR	User audit trail (the user ID must be configured before the CARLa scripts are run)
CKALFVW	RACF violations and warnings

Chapter 8. RACF Offline

The RACF Offline function available with zSecure Admin allows you to execute and test most RACF commands against an offline or inactive RACF database.

The following terms are used to distinguish between the inactive RACF database and the system RACF database.

- *Offline RACF database* and *Offline RACF environment* describe the inactive RACF database and its environment.
- *System RACF database* and *System RACF environment* describe the RACF database that is currently used by the system for all regular verifications.

For most installations, the System RACF database consists of a primary and secondary (backup) database. The Offline RACF database does not provide such an automatic backup feature.

In the standard RACF environment, all RACF verifications (like logon and access to data sets) are verified using the information in the primary RACF database. All updates are normally performed against both the primary and the secondary (backup) RACF database. Thus, if a RACF administrator issues a command to add a profile, the new profile is added to both databases.

Using RACF Offline you can direct all RACF *commands* to a third or alternate RACF database. RACF *access verifications* are not affected and are still performed against the System RACF database. Thus, the Offline RACF environment applies only to the RACF commands. RACF Offline must be explicitly activated before it is available. After the Offline RACF environment is stopped, the regular System RACF environment is re-established. Currently, you *cannot* use the Offline RACF environment for logon and resource access verification. These functions are always performed against the System RACF environment.

As an illustration of the difference between the handling of *commands* and *verifications*, consider the situation when a user issues the ISPF command while in the Offline RACF environment. All standard ISPF functions remain available. Depending on the type of actions being performed while in ISPF, either the System RACF database or the Offline RACF database is used. For example, when the user uses Option-1 to BROWSE a data set, the System RACF database is used to verify READ access to the data set. If the user uses Option-6 or the RACF panels to issue a RACF command, the Offline RACF database is used. The main thing to remember is that only the RACF commands are affected by RACF Offline.

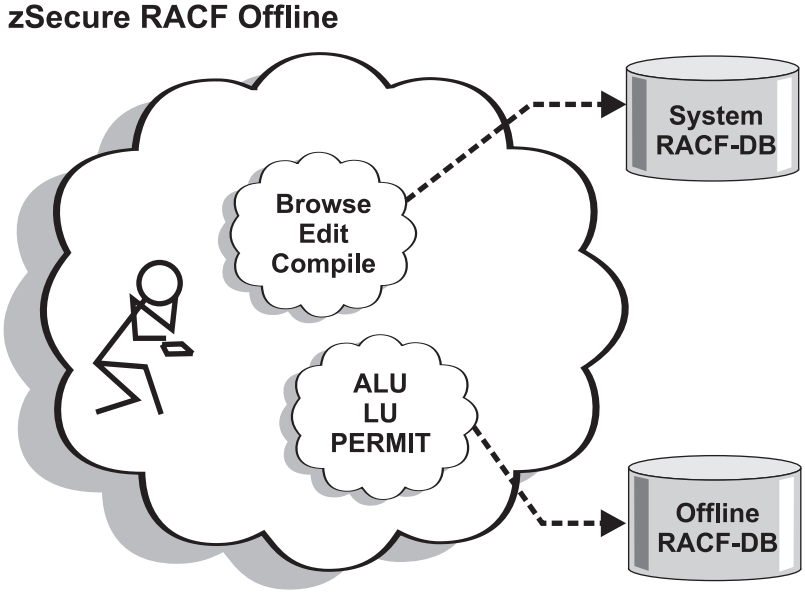

Figure 472. RACF commands and access verification in Offline RACF environment

The environment, as set up using the B8RACF command, can be compared with an RRSF environment. Whenever you are in the Offline RACF environment, it is like automatically adding the AT keyword to each and every RACF command. It looks like the command is always sent to another system, which uses another RACF database.

The Offline RACF environment supports most RACF commands and supports some non-RACF commands. The following RACF commands are not supported in the Offline RACF environment.

- Operator RACF commands
- RACLINK command
- RVARY command
- SETROPTS command

The ISPF command is an example of a non-RACF command that is supported in the Offline RACF environment. You can still run most non-RACF commands inside the Offline RACF environment by first running the ISPF command and then using the ISPF option 6 to issue all other commands.

You can start the environment interactively under TSO, but you can also run the B8RACF command in a batch job. All functions are available both in TSO and in batch. For additional information, see “The environment” on page 596.

To begin using the Offline RACF environment, issue the B8RACF command. Next, when prompted, run the LOGON command. In the Offline RACF environment, the LOGON command builds a security environment based on the authorizations in the Offline RACF database. If you do not use the LOGON command, the USERID of the terminal user must also be present in the Offline RACF database, or the USERID must have system-SPECIAL authority. See “Logging on to the Offline RACF database” on page 600.

Functions and usage

After starting RACF Offline, a user experiences two different environments. The regular System RACF environment that is used for logon and access verification, and the Offline RACF environment that is used for all RACF commands. As soon as the user exits B8RACF, the RACF commands use the System RACF database again. The B8RACF command facilitates switching between different RACF databases.

To avoid confusion, use the Offline RACF environment for dedicated sessions. If you are in the Offline RACF environment, the output from the LD command shows a different RACF profile than the one that is used for data set access verification which might be confusing. Or, for example, the LD command can show `your access=alter` at the same time that you get access violation messages showing the same profile. Before using B8RACF on a daily basis, try it and learn about the confusing aspects of the mixed environment within ISPF.

Figure 473 illustrates the use of B8RACF to establish an Offline RACF environment.

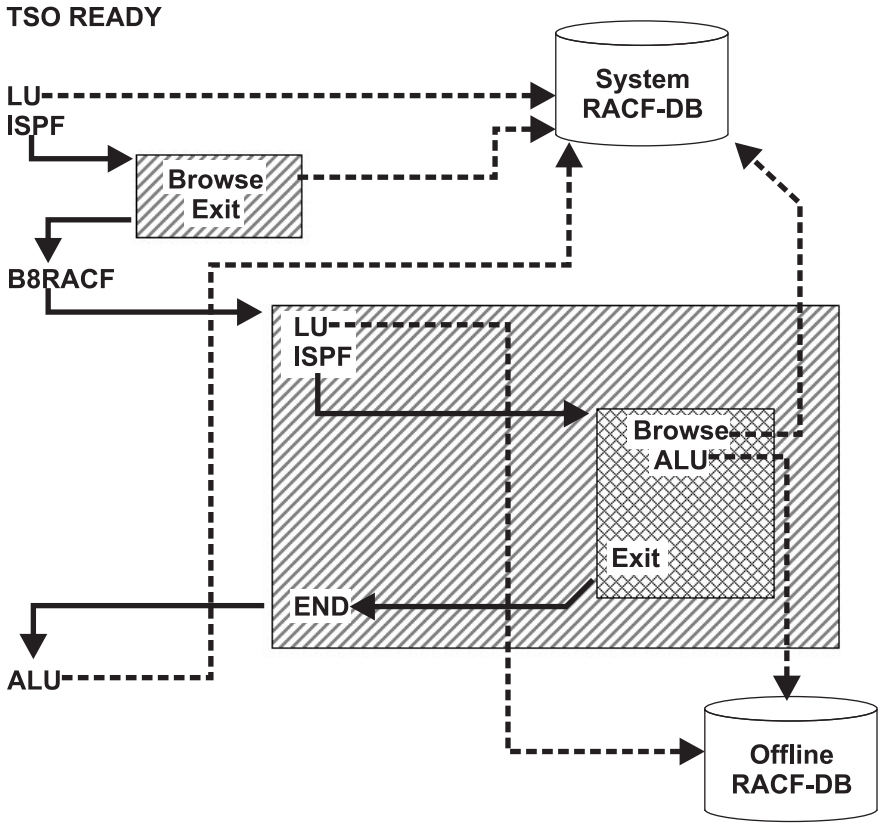

Figure 473. RACF commands and access verification in Offline RACF environment

In Figure 473, several commands are issued, and the flow of commands follows the solid arrows. The dotted arrows show use of a particular RACF database. The backslashes (\\\) box indicates the ISPF environment, and the forward slash (///) box indicates the B8RACF environment. The crosshatched (XXXX) box indicates use of ISPF inside B8RACF. Access verification follows these processing steps:

1. The first LU command is issued in TSO READY mode (line mode) and accesses the System RACF database (dotted arrow).

2. Inside the first ISPF session, the System RACF database is used as well. After issuing the B8RACF command, the LU command accesses the Offline RACF database.
3. As shown inside the crosshatched (XXXX) box in Figure 473 on page 595, the BROWSE function of ISPF still involves the System RACF database, and the ALU uses the Offline RACF database.

In summary, access verifications always use the System RACF database. RACF commands go to the System RACF database when operating outside of B8RACF and to the Offline RACF database when inside B8RACF.

The environment

The environment that is set up using the B8RACF command can be compared in some respects to an RRSF environment. Whenever you are in B8RACF, it is like automatically adding the AT keyword to each and every RACF command. It looks like the command is always sent to another system, which uses another RACF database.

In the Offline RACF environment:

- Access checking is done against the System RACF database.
- Commands are directed to the Offline RACF database.
- Commands are parsed according to the settings of the active system.

  This includes both the SETROPTS settings (GENERIC, GENCMD and EGN) and the dynamic parsing (as set by the IRRDPI00 command). A fully initialized version of RACF on the active system is required.
- The Custom Data fields (in USER and GROUP CSDATA segments) as defined in the CFIELD profiles are used from the active System RACF database. These definitions are installed into common system storage using the IRRDPI00 command. RACF Offline does not provide an option to use IRRDPI00 to activate the Custom Data definitions from the Offline RACF database. Therefore, inside RACF Offline, parsing and handling of Custom Data fields is done using the definitions as installed from the System RACF database.
- Field level access checking uses the profiles as defined in the Offline RACF database. Previous versions of the RACF Offline program used the in-storage authorizations from the System RACF database. This behavior was changed in IBM Security zSecure Admin release 1 version 10.
- Other RACF command authorizations are done using information from the Offline RACF database.
- Profile actions that are not commands are directed to the System RACF database. For example, in the Offline RACF environment when you delete a data set that is protected by a discrete profile, that profile is deleted from the System database.
- In releases of the RACF Offline program before version 1.9.1, updates made via the IBM Security zSecure Admin CKGRACF function were directed to the System RACF database. Starting with version 1.10, these type of updates are directed to the Offline RACF database. Authorization for the CKGRACF function is obtained from the Offline RACF database.

Activating

The RACF Offline functions are not available until the program is explicitly activated by using the B8RACF command. The B8RACF command can be executed interactively under TSO, but you can also run the command in a batch job. If you submit a batch job, the job is executed in the standard System RACF environment.

The batch job also needs to explicitly switch to an Offline RACF environment. Switching environments in a batch job can be done by using either of the following methods.

Method 1

Issue the B8RACF command as a regular command under the TSO batch environment.

If you use this method, you should use one of the alternative TSO programs IKJEFT1A or IKJEFT1B instead of the default IKJEFT01 program.

When using IKJEFT1A, the entire job is terminated if an error occurs that prevents the B8RACF command from executing. This results in flushing all B8RACF RACF commands. If the default TSO program IKJEFT01 is used, TSO execution would continue, and all RACF commands would be executed against the System RACF database. To prevent this from happening, one of the alternative programs should be used. The following example executes the B8RACF command as a TSO batch job.

```
//RUNIT    EXEC PGM=IKJEFT1A
//STEPLIB  DD DISP=SHR,DSN=BYBG.ROFFLINE.SB8RLOAD
//SYSTSPRT DD SYSOUT=*
//SYSTSIN  DD *
 B8RACF
 ALU BCSCTST REVOKE
 END
```

Method 2

Issue the B8RACF command in a job step program.

The B8RACF command should be specified in the `PGM =` keyword on the EXEC statement of the job step. The B8RACF program uses the same *input* and *output* `ddnames` as used under TSO (respectively SYSTSIN and SYSTSPRT). If an error occurs in the B8RACF command, the remaining commands in the SYSTSIN stream are automatically discarded. The following example executes the B8RACF command as a JCL job step.

```
//RUNIT    EXEC PGM=B8RACF
//STEPLIB  DD DISP=SHR,DSN=BYBG.ROFFLINE.SB8RLOAD
//SYSTSPRT DD SYSOUT=*
//SYSTSIN  DD *
 ALU BCSCTST REVOKE
```

The Offline RACF environment that is started from a TSO user or a batch job is never automatically propagated to other jobs. At first, when you are frequently using batch jobs to execute RACF commands, you might be confused. RACF commands are only directed to the Offline RACF database after you have explicitly activated the environment.

Supported file definitions for the B8RACF command

The following DD statements (or file allocations) are used by RACF Offline.

STEPLIB

STEPLIB or JOBLIB identifies the library containing the RACF Offline program modules.

SYSTSPRT

Defines a sequential message output data set. SYSTSPRT can refer to a sequential data set, a member of a partitioned data set, or a SYSOUT data set. The data set can have variable or fixed length records. Use of a sufficiently large logical record length (for example 255 bytes) ensures that output records are not folded across multiple output lines.

SYSTSIN
Defines a sequential command input data set. This file must contain RACF or RACF Offline supporting commands as described in section "The B8RACF command and Control commands" on page 612.

SYSTSIN can refer to a sequential data set, a member of a partitioned data set, or SYSIN data set. The data set can have variable or fixed length records. Use of 80-byte fixed length records is convenient for most situations. Continuation lines are supported using the TSO convention of a + (plus) or - (minus) as last non-blank character in the available input line. The following processing rules are used for SYSTSIN fixed and variable length data sets:

Fixed length data set (FB) – The last 8 bytes of the record are treated as a sequence number and ignored.

Fixed length data set with ASA control characters (FBA) – The first byte of the record is treated as a carriage control character and ignored.

Variable length data set (VB) – The first 8 bytes of the record are treated as a sequence number and ignored.

Variable length data set with ASA control characters (VBA) – The first 9 bytes of the record are treated as a sequence number, followed by a carriage control character and ignored.

SYSPRINT
Defines an internal work file. The ddname is freed and reallocated by the B8RACF program.

INDD*n*
Defines the RACF input data set that makes up the RACF database. These ddnames are used for the RACF database as specified in the RACFDB command. If no RACFDB command is issued, the program assumes that INDD*n* defines the Offline RACF database to be used.

OUTDD
Defines an internal work file. The ddname is freed and reallocated by the B8RACF program.

B8RPARM
Defines a sequential parameter input data set. This file must contain RACF Offline control commands as described in section "The B8RACF command and Control commands" on page 612. B8RPARM can refer to a sequential data set, a member of a partitioned data set, or SYSIN data set. The data set can have variable or fixed length records. Use of 80-byte fixed length records is convenient for most situations. The line continuation, sequence number, and ASA control characters for SYSTSIN also apply to B8RPARM.

B8ROPTnn
Defines a sequential parameter input data set. This file must contain RACF Offline control commands as described in section "The B8RACF command and Control commands" on page 612. B8RPARM can refer to a sequential data set or a member of a partitioned data set. The data set must have fixed length records of 80 characters. Continuation lines are not supported and all 80 characters are interpreted as part of the command.

Using RACF and non-RACF commands

As mentioned in the previous section, the Offline RACF environment only supports a limited set of commands. However, because ISPF is one of the supported commands, you can execute all other commands from inside ISPF. The

following non-RACF commands are also directly supported in B8RACF: LOGON, END (or EXIT), and several internal commands (logging control and switching of the Offline RACF database).

The END command signals termination of B8RACF. See “Supporting commands” on page 615 for more information on these commands.

The following RACF commands are *not* supported in the Offline RACF environment:

RVARY
The RACF RVARY command is used to switch or (in)activate RACF databases for the entire system. The equivalent function in is provided using the B8RVARY command. (See “**B8RVARY**” on page 617.

SETROPTS
The SETROPTS command is not supported because it is not currently feasible to translate its functionality to the Offline RACF environment. In addition, the potential impact of accidentally issuing the SETROPTS command in the wrong environment is an unacceptable risk.

RACLINK
Because the RACLINK command is mainly executed in the RACF address space, it is currently not enabled in the Offline RACF environment. Issuing the command results in a request to the RACF address space which would subsequently update the System RACF database instead of the Offline RACF database. Because this is not the desired effect, the RACLINK command is not supported.

Preparing a RACF database for RACF Offline use

You can use any RACF database as an RACF Offline database except the active System RACF database. In addition, do not use a RACF database that is currently in use by a different z/OS system or by a z/VM system. Through shared DASD, you can use a foreign database, but for serialization reasons it is not a good idea to use one. However, you can use a foreign database for recovery when no other system that can use it is active. Also, be aware that most foreign systems have a primary/backup database combination. If you are working with a system that uses a primary/backup database combination and update only one of the databases, the primary and backup databases will be out of sync. To resynchronize the databases, you copy the updated database over the other one before you IPL any system that uses the databases.

During RACF Offline initialization, the RACF Offline code checks that the database is not incorrectly shared with any other system. This is implemented via `IRRPLEX_<sysplex-name>` profiles in the GXFACILIT class as described in "Guarding against data corruption resulting from incorrect database" in the *Security Server RACF System Programmer's Guide*. If the Offline RACF database contains profiles indicating the RACF database has been used in data sharing mode, RACF Offline issues a warning message and a prompt to continue. If you are sure that the RACF Offline database is no longer part of an active data sharing group, you can respond with *continue*. In that case, RACF Offline verifies that you have at least CONTROL access to the resource `B8R.RACFDB.offline-database-name`. If RACF Offline does not detect any profiles indicating use of the Offline RACF database as part of a data sharing group, processing continues without any prompts to the user. To record that the Offline RACF database is now used by RACF Offline, an `IRRPLEX_<sysplex-name>` profile is added indicating non-data sharing mode. If RACF Offline ends processing normally, with no abends, the `IRRPLEX_<sysplex-name>` profile is removed again. The `sysplex-name` used by RACF Offline is `B8RACF`

followed by two numeric characters representing the RACF Offline session. An example of such a sysplex-name is B8RACF01.

After creating a fresh copy of the RACF database, you might need to respond to the B8R351A prompt to continue. To avoid being prompted each time that you use this database, use a USERID with system-SPECIAL to remove the IRRPLEX_* profiles in the GXFACILI resource class.

If the Offline RACF database is activated as a System RACF database on another system (either via IPL or RVARY), the other system might detect that RACF Offline is using the Offline RACF database in a non-data sharing mode (indicated via sysplex name B8RACFnn). If this situation is detected, the other system issues one or more prompts to the console operator. Of course, these console messages are only issued if the Offline RACF database is still in use, or if RACF Offline failed to remove its IRRPLEX_sysplex-name profile. These console messages are only available for z/OS Release 1.10 or later.

Note: An inappropriate continue response to the console messages will most likely result in corruption of the Offline RACF database.

When using an existing database, make sure that the templates in that database are on a level that is supported by the level of RACF on the active system. Using downlevel templates might result in error messages such as IRR51004I, IRR51011I, or IRR52115I, or in ABEND 483-024. If these errors occur, upgrade the templates by running IRRMIN00 with PARM=UPDATE against the Offline RACF database. Use the IRRMIN00 utility and the templates from the system where you are using IBM Security zSecure Admin RACF Offline.

If you are not using a foreign database, copy an active System RACF database or initialize a new database for use as an Offline RACF database. Normally, you use IRRUT200 to copy the active System database. If the active System database is physically split into multiple databases, you might need to use IRRUT400 for the copy process. RACF Offline requires that the Offline RACF database is physically split in the same way as the active System RACF database. If the source database uses a different physical split other than that used on the system where you want to execute, copy the database using IRRUT400 and create the output data sets such that the data sets match the physical split used on the execution system.

Logging on to the Offline RACF database

To run the B8RACF command, the user must be logged on the system. If the terminal user does not explicitly log on inside the Offline RACF environment, the authorization of the user in the System RACF database is used for the Offline RACF database. This authorization can cause several problems if the terminal user is not defined in the Offline RACF database. The most common symptom of such problems is the error message:

```
ICH51011I RACF MANAGER PROCESSING ENDED DUE TO ERROR. RETURN CODE = 24
```

This error message indicates that RACF was unable to obtain the authority of the current user to execute the requested command. Other possible error messages include:

```
ICH51003I NAME NOT FOUND IN RACF DATA SET
```

which often indicates that a userid or group that is used as the default in a RACF command (for example, the default group for the current user) does not exist in the Offline RACF database.

If the terminal user has the system-SPECIAL attribute, most of the preceding problems are not immediately obvious. However, the system-SPECIAL attribute must be assigned in the System RACF database to be effective, which is impractical in most situations.

The real solution to these problems is to start issuing the RACF Offline commands with a LOGON command to build an authorization environment by using the information from the Offline RACF database. The simplest form of the command is `LOGON` without any additional parameters. When this command is issued, the current `userid` is used to log on to the Offline RACF database. If the current userid has insufficient authority or is not defined, use the extended form of the command, `LOGON` *`userid`*`/` for example. This extended command prompts for the password and logon to the Offline RACF database using the specified userid. If you are properly authorized in the System RACF database, you are able to use the LOGON command with the SPECIAL keyword. If you use the SPECIAL keyword, your session uses the RACF system-SPECIAL attribute while using the Offline RACF database. The system-SPECIAL attribute is temporary and is used only if the SPECIAL keyword is used with the LOGON command. See "Supporting commands" on page 615 for the complete syntax of the LOGON command.

Switching between RACF databases

You can use the B8RVARY command to switch to another Offline RACF database without leaving the B8RACF command environment. The B8RVARY command can be used directly inside B8RACF, but the command is also available under ISPF. The B8RVARY command can be used interactively or through existing option files.

Switch RACF databases using the B8RVARY command interactively

Use this interactive procedure to switch to RACF databases without leaving the B8RVARY command environment.

1. Run the B8RVARY command.
2. When prompted, confirm that you want to change the Offline RACF database.
3. If you respond with `YES`, the current Offline RACF database is closed and freed.
4. When prompted, enter the B8RACF Control commands.

   The most likely commands to use are the RACFDB command and the LOGDS command.
5. When the specification of the Offline RACF environment is complete, use the END command to stop the prompts.

Switch RACF databases using an option file

Instead of using the B8RVARY command interactively, you can also use a prepared option file. The option file contains the required B8RACF control commands to switch to another RACF database.

The preallocated configuration files are easier to use, especially when you need to switch frequently between different Offline RACF databases. The preallocated configuration files are also used for the REPLAY function. See "Replaying previously issued commands" on page 603.

The option file is a data set that contains B8RACF Control commands as shown in the following example:

```
/* Options file for old z/OS 1.5 database */
racfdb 'sys1.racf15'
logds 'sys1.racf15.b8rlog'
smf id($150)
```

To use this predefined environment, allocate the data set to the ddname B8ROPT*xx*, where *xx* is any two alphanumeric or national characters as shown in the following example.

```
alloc da('BYBG.B8ROPT.CNTL(RACF15)') fi(B8ROPT15) shr
```

In this example we assume that the data set containing the B8RACF Control commands is the member RACF15 in partitioned data set BYBG.B8ROPT.CNTL. The B8ROPT*xx* file to be used is B8ROPT15. After allocating the file, it can be used in the B8RVARY command with the SELECT keyword.

```

Figure 474. Using the B8RVARY command with the SELECT keyword

Logging for RACF Offline commands

You can maintain a log of all RACF commands issued during a B8RACF command session. To enable this function, you need a predefined log data set that can be designated as the log file. Then, use the LOGDS control command to specify the log file.

When setting up the data set to be used for logging, the following requirements and processing considerations apply:

- Define the log data set before using the LOGDS command to specify the log file.
- Specify the data set as VB (variable blocked) with LRECL 255 (record length of 255 bytes).
- Optional: Specify a block size of 27998 for the block size which is the system determined optimum block size for 3390 disks).

The following process considerations apply to the LOG file.

- The LOG data set is used in extend mode, which means that all logged commands are added to the end of the LOG data set.
- Using default data set characteristics, the LOG data set can contain on average 10000 commands per cylinder on disk.

- As a best practice, use one LOG data set for each Offline RACF database so that the LOG contains all changes relevant to a particular database. You can add the data sets easily by adding a LOGDS command in either the B8ROPT module, the B8RPARM file, or the B8ROPTxx control files.
- If the LOG data set is full, logging is suspended. To keep the log from getting full, either allocate a sufficiently large LOG data set, or RESET the LOG file periodically.

Replaying previously issued commands

The LOG data sets can also be used as command source for the B8REPLAY command. The B8REPLAY command specifies a preallocated B8ROPT*xx* control file.

```
B8REPLAY SELECT(xx)
```

The B8ROPT*xx* control file is scanned for a LOGDS command. The LOGDS command designates the source for the commands that should be executed against the current Offline RACF database. The following example shows a B8ROPT*xx* control file.

```
/* Sample RACF Offline Options file */
RACFDB 'BYBG.ROFFLINE.TESTDB'
LOGDS  'BYBG.ROFFLINE.TESTDB.LOG'
SMF ID($B8R)
```

To avoid problems, command logging is temporarily suspended during replay of commands.

You can also use the B8REPLAY command to execute previously prepared RACF commands by creating a B8ROPTxx file containing only the LOGDS statement. The LOGDS statement should point to an existing data set containing the commands you want to issue. The data set should have the attributes VB(255). Data sets with a fixed record length are currently not supported. The records should not contain line numbers, and cannot have any continuation records.

Auditing

Most of the standard RACF command processors write SMF records during processing. It is almost impossible to distinguish the SMF records written for an update to the Offline RACF database from those written for an update to the active System RACF database. To enable identification, you can use the SMF command to mark SMF records as written during a session. Some of these options apply to all SMF records. Others only apply to the RACF SMF records. The best option is to modify the SMF ID for the affected records.

The modification of the SMF records is performed by the dynamic activation of the SMF record exit routines (IEFU83, IEFU84, IEFU85). However, this is dependent on the installation SMF options. For this reason, you should always specify EXITS(IEFU83,IEFU84,IEFU85) in the active SMFPRM*xx* member of PARMLIB for all subsystems (or for the entire system). These exits should be specified, even if the installation itself does not provide any exit routines. In the absence of any installation provided SMF exits, the IBM-provided dummy modules in LPALIB are used.

Because RACF Offline uses the dynamic exit facility, the installation should also use dynamic SMF exits (defined by PROG*xx* in PARMLIB) instead of static routines linked into LPALIB. Of course, this only applies if the installation requires SMF exits for exit points IEFU83, IEFU84 or IEFU85.

Using RACF Offline

This section provides some guidelines for selecting the various control command options, depending on the intended functionality. "RACF Offline commands" on page 611 describes the various control commands. For information about how some of these can be issued automatically at every invocation of the B8RACF command, see *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

When you start using the B8RACF command, B8RACF processes control commands from two input sources. One input source is created during installation, the other is variable, and can be selected by the user. During installation, the B8ROPT module is assembled and included in the B8RACF module. It is always executed before other processing takes place. We recommend that the module contain an SMF command to indicate default processing of SMF records created during usage. The SMF command has several options to uniquely identify such SMF records. If no SMF command is used, the RACF SMF records created during use of RACF Offline cannot be distinguished from those created by RACF commands outside RACF Offline. Because this is undesirable, we recommend that the SMF Control Command is used in B8ROPT. Use of the SMF command in B8ROPT is not RACF controlled. This means that the user does not need any RACF authorization for the SMF option specified by B8ROPT to become effective. Optionally, the B8ROPT module can contain a RACFDB command, and a LOGDS command to specify defaults for the RACF database and log file. If the user does not have sufficient authority to use the selected database as the Offline RACF database, the command fails.

At the discretion of the user, it is also possible to include control commands in the B8RPARM file. When this file is allocated, its contents are used to override the options specified by B8ROPT. One of the differences between the use of B8ROPT and B8RPARM is that the commands used in B8ROPT are not subject to the command-authorization-verification process, while those in B8RPARM are.

Allocating the `B8RPARM` file to the terminal provides the greatest flexibility. This allocation allows the user to dynamically select which RACF database and which SMF options to use.

For both uses of the `B8RPARM` file, the terminal user must be authorized for the options specified. If the terminal user lacks sufficient authorization, the options specified in `B8ROPT` cannot be overruled, and the defaults are enforced. This is the main reason that use of the SMF command in `B8ROPT` is strongly advised. It provides a way to ensure that only selected users are permitted to modify the SMF processing options.

In respect to the preceding considerations, the following different uses are anticipated.

Controlled usage
The B8ROPT module specifies the SMF options, and also includes a RACFDB command to specify the RACF database to be used. By default, the B8RPARM file is *not* allocated. The users do not have any authorization to specify any SMF processing options, and thus the installation specified options are used. The intended terminal users are explicitly authorized to use the selected RACF database. Users who are not permitted to access functions could be excluded from access to either the `B8R.RACF.OFFLINE` profile, or from access to any `B8R.RACFDB.`*dsname* profile. Without access to *any* Offline RACF database, RACF Offline cannot be used.

If the user allocates the B8RPARM file, she would still not be able to select databases other than the ones explicitly permitted by B8R.RACFDB.dsname profiles. Lacking sufficient authorization, the SMF options could not be modified either.

The suggested access to the control profiles for this type of user would be:

```
B8R.RACF.OFFLINE                                READ
B8R.RACFDB.the-database-specified-in-B8ROPT     UPDATE
B8R.SMF.**                                      NONE
```

User-specific default use

The B8ROPT module specifies the SMF options, and also includes a RACFDB command to specify the default RACF database to be used. Users would normally allocate the B8RPARM file to an input data set containing the appropriate RACFDB command to select the database intended for their use. The RACFDB commands should point to an existing RACF database. The terminal user needs access to the B8R.RACFDB.*dsname* profile controlling usage of the RACF database specified by their B8RPARM file.

If the user changed the allocation of the B8RPARM file, she would still need sufficient access to the selected RACF database.

The suggested access to the control profiles for this type of user would be:

```
B8R.RACF.OFFLINE                                READ
B8R.RACFDB.the-database-specified-in-B8ROPT     UPDATE
B8R.RACFDB.other-approved-database              UPDATE
B8R.SMF.**                                      NONE
```

Flexible usage

The B8ROPT module specifies default options for both the SMF options and the RACF database to be used. The B8RPARM file is allocated to the terminal. During startup of B8RACF, the user enters additional control commands to specify SMF processing options, and to specify the RACF database to be used. Because the SMF command does not have an option that resets the processing to do nothing, the SMF records are always processed in some way. (Processing includes suppression of those records.) The terminal user must be authorized to use the RACF database selected for usage.

The suggested access to the control profiles for this type of user would be:

```
B8R.RACF.OFFLINE                                READ
B8R.RACFDB.the-database-specified-in-B8ROPT     UPDATE
B8R.RACFDB.**                                   UPDATE
B8R.SMF.**                                      UPDATE
```

In summary, by selecting the appropriate defaults in B8ROPT, in combination with prepared B8RPARM files and appropriate RACF profiles, the installation accommodates different types of users. It is anticipated that most installations will use all three methods, depending on the need of their users.

Usage scenarios

Several applications for exist. This section describes some of the more common situations.

Preparing large updates

This section discusses two large update processes, RACF database merge and an ACF2 to RACF conversion which would typically require significant system downtime. The example shows how can be used to accomplish the same tasks while minimizing downtime.

RACF database merge: Merging RACF databases can be done using the MERGE function of IBM Security zSecure Admin. The output of the MERGE function is a stream of RACF commands that needs to be executed. Usually, the commands are executed on the target system to modify it in such a way that the profiles from the source system are added. The resulting database is then used during a test period. If the test fails, you probably discard the RACF database, and try again. The alternative to discarding is a one-time merge, followed by incremental corrections. You are now faced with a dilemma: If you discard the RACF database, you need significant time on a dedicated system to rebuild it (possibly several times). If you use the one-time merge approach, you need significant testing beforehand to ensure that the resulting RACF database is acceptable for production usage. Either way, a dedicated system is needed during a significant period.

Alternatively, RACF Offline can be used on the existing target system. A copy of its RACF database is used as an Offline RACF database, and the stream of RACF commands from the MERGE function is executed. In the discard and iterate approach the following steps are used:

1. To start the test-period, the Offline RACF database is activated using either an IPL, or using a sequence of RVARY and RENAME commands.
2. At the end of the test, the inverse steps are executed to reactivate the previous System RACF database.
3. After the test, the input to the merge tool is tuned, and a fresh copy of the target RACF database is used for the next iteration.

In the *incremental correction* approach, the following steps are used:

1. After executing the stream of RACF commands from the merge tool on the Offline RACF database, you can use various reporting tools to inspect the resulting RACF database.
   - and regular RACF list commands
   - displays and reports
2. Using the reports about the Offline RACF database, you make manual adjustments to the profiles.
3. When the fine-tuning of the profiles is completed, the Offline RACF database is activated as the RACF System database.
4. If the user passwords need to be updated, you can run a final MERGE of all users, and select the CKGRACF commands that set the password and last-use dates.

ACF2 to RACF conversion: Another process that can require a lot of system downtime is conversion from a different security product such as ACF2. The output of the conversion process is again a stream of RACF commands that needs to be executed. Usually the entire conversion project involves building and testing the RACF system several times. Without RACF Offline, these commands must be executed on the System RACF database. Because the purpose of these commands is to define the group, user and resource profiles, the system cannot be used by regular users during this period. That means that the time available for testing is shortened significantly. One possibility to avoid this situation is to create a separate LPAR just for the execution of this stream of RACF commands. After building the new RACF database, the database is then moved to the test LPAR, and activated (either using IPL, or using a sequence of RVARY and RENAME commands).

When RACF Offline is available, an alternative exists. Instead of creating a separate LPAR, RACF Offline is used on the existing test LPAR. Now the commands are executed against an Offline RACF database. This can be done at the same time that the test LPAR is used for other work. After building the refreshed RACF database,

it can be activated as the System RACF database using IPL, or a sequence of RVARY and RENAME commands. The activation process should also involve creation of a backup RACF database.

Testing new profiles

In a customer environment a project was started to reduce the number of data set profiles. They used the *Report Redundant* function to compare each profile to its next-best generic. For example, when the profiles shown in Figure 475 are present, Profile 2 and Profile 1 are compared and the entry `XYZZY` on the access list is flagged as major difference. The entry `XYZZY` makes Profile 2 *non-redundant*. It is that entry that makes the profile different from the next best profile. This difference is what makes the profile *contribute* something to the security definitions. The installation (often the security administrator) has the option to decide that this contribution is *really* significant, or just a fluke that can be discarded.
Other observations about the list of profiles shown in Figure 475 are as follows:

```
1)   ABCD.**          UACC(NONE)      READ(XYZ,QWAS)                  AUDIT(FAIL(READ))
2)   ABCD.A*.**       UACC(NONE)      READ(XYZ,QWAS)  UPDATE(XYZZY)   AUDIT(FAIL(READ))
3)   ABCD.PROD.**     UACC(NONE)      READ(XYZ)                       AUDIT(FAIL(UPDATE))
4)   ABCD.TEST1.**    UACC(NONE)      READ(XYZ)       UPDATE(XYZZY)   AUDIT(FAIL(READ))
5)   ABCD.TEST2.**    UACC(NONE)      READ(XYZ)       UPDATE(XYZZY)   AUDIT(FAIL(READ))
6)   ABCD.TEST3.**    UACC(NONE)      READ(XYZ)       UPDATE(XYZZY)   AUDIT(FAIL(READ))
```

Figure 475. Sample profiles

- ACL entry `XYZZY` makes Profile 2 different from Profile 1.
- ACL entry `QWAS` makes Profile 3 different from Profile 1. AUDIT setting `FAIL(UPDATE)` makes Profile 3 different from Profile 1.
- ACL entries `QWAS` and `XYZZY` make Profile 4 different from Profile 1.
- ACL entries `QWAS` and `XYZZY` make Profile 5 different from Profile 1.
- ACL entries `QWAS` and `XYZZY` make Profile 6 different from profile 1.

When analyzing the preceding profiles, *Report Redundant* simply reports several reasons that five profiles are non-redundant. It does not give any recommendation on how to proceed. The installation might decide to reduce the number of profiles by using methods similar to the following methods.

Method 1

Add ACL entry `XYZZY` to Profile 1 and add ACL entry `QWAS` to Profiles 4, 5, and 6. This would make Profiles 2, 4, 5 and 6 redundant, and Profile 3 almost redundant.

Method 2

Add Profile 3a `ABCD.TEST%.**` like Profile 4 `ABCD.TEST1.**`. This addition would make Profiles 4, 5, and 6 redundant.

When consolidating the profiles, the administrator needs some confirmation that it indeed has the intended effect and that no unintended data sets were affected by this change.

When using Method 2, the process could be:

1. Use `IRRUT200`, to make a copy of the production RACF database for use as Offline RACF environment.
2. On the displays, use the LR line command to see which data sets are covered by a selected profile. Do this for both the System RACF and the Offline RACF database.
3. After defining the new profiles, recreate and analyze the redundancy report.

4. Delete the now redundant profiles and use the LR line command to verify that only the intended resources were affected.

When using Method 1, the analysis is less complex because the approach only increases access by adding entries to access lists. Using this method, there is little chance of negatively impacting the production environment. However, this is a non-preferred solution because it requires granting unnecessary access.

Testing profiles on multiple systems

In another customer environment, the customer wanted to gradually synchronize RACF profiles on three systems. The customer wanted to analyze the effects of adding or changing profiles on all affected systems before actually implementing the changes. RACF Offline provides the command logging facility and the B8REPLAY command to quickly perform those tasks. The following scenario could be implemented:

1. Start RACF Offline.
2. Reset the LOG file.
3. Issue RACF commands to the default Offline RACF database.
4. Switch to an alternative Offline RACF database.
5. Reset the LOG file.
6. Replay the commands from the default LOG.
7. Issue additional commands to verify changed profiles in context.
8. Switch to the third Offline RACF database.
9. Reset the LOG file.
10. Replay the commands from the default LOG.
11. Issue additional commands to verify changed profiles in context.

The following set of commands illustrates the preceding scenario.

```
B8RACF
B8RACFLG RESET
AD 'some.profile'
B8RVARY SELECT(02)
B8RACFLG RESET
B8REPLAY SELECT(01)
LD DA('some.dataset') gen
B8RVARY SELECT(03)
B8RACFLG RESET
B8REPLAY SELECT(01)
LD DA('some.dataset') gen
```

Using an iterative approach, the commands can be refined to have the desired effect in all three environments.

Of course, using prepared batch jobs and submitting the commands to three different target systems is also possible. However, this approach involves one of the following: issuing the commands directly on the production target systems, the use of three test LPARs, or complicated switching of the System RACF database on one test LPAR. Using the process could be implemented in a single batch job or TSO session on a regular test or production system.

System recovery

This application of requires some understanding of the usage of shared disks and the RVARY command to activate or switch RACF databases. Using for recovery purposes significantly reduces system outage time, by reducing the number of IPL's required, and by simplifying the recovery process.

This scenario is based on a multiple LPAR environment with the possibility to share disks between the LPARs. The scenario does not apply to a sysplex

environment, where RACF data sharing has been activated. In the scenario an erroneous RACF command has been issued that prevents the system from IPLing. An example of such a command would be the definition of a PROGRAM profile covering LINKLIB modules. Since OW50327, RACF uses access READ for profile '*' or '**' for SYS1.LINKLIB if a `UACC(NONE)` denies access. However, this APAR does not address situations where another profile (like I*) prevents access, or where the `UACC(READ)` is overruled by an ACL entry (such an ACL entry will not prevent the SYSTEM from starting, but it can have severe impact on major subsystems like VTAM, TCPIP and TSO).

The APAR suggests IPLing with an older (backup) RACF database, and using a sequence of RVARY commands to re-establish the recent RACF database. As soon as the recent RACF database is active, corrective RACF commands can be issued. The older database is used to bypass the IPL problem, and the recent database is quickly re-established to avoid losing profile updates like user password changes.

However, the disadvantage of this recovery scenario is that it requires either some preparation, or complex ad-hoc procedures. For example, you need to prepare an alternative RACF data set name table pointing to the older backup copy. Failing that, the recovery will involve stand-alone utilities to recover the backup copy of the RACF database without destroying the recent RACF database. A single-disk disaster recovery volume would remove the awkwardness of stand-alone utilities in this type of situation.

Instead of IPLing an older (backup) database, it is also possible to use shared disks and to correct the problem. Figure 476 illustrates the environment.

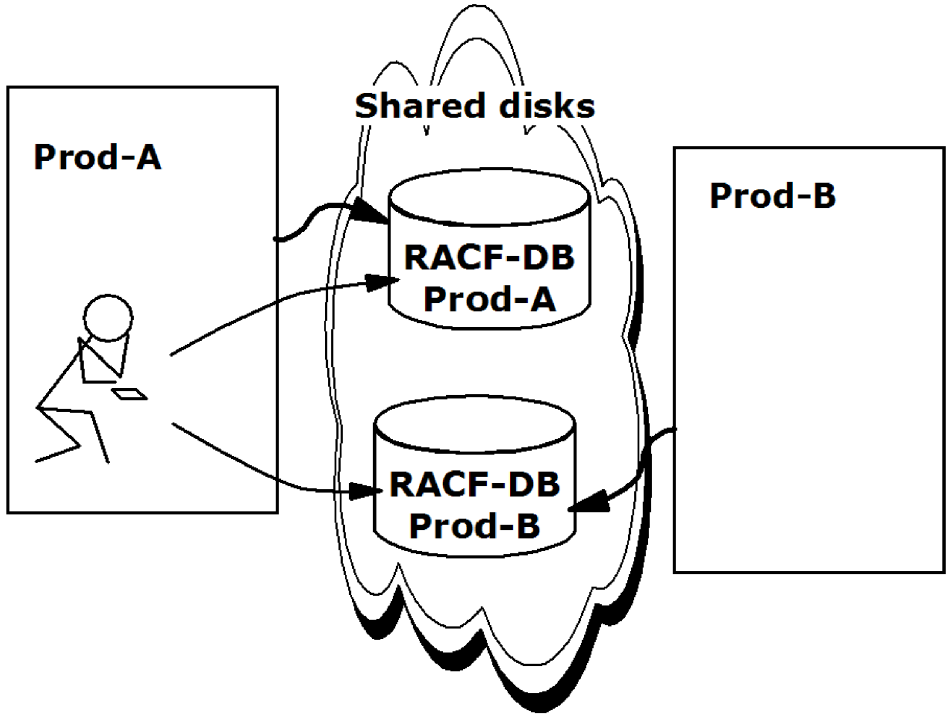

Figure 476. Recovery by multiple LPARs using shared disks

The RACF administrator, who is logged on to the `PROD-A` system can issue RACF commands that are executed on the current system using regular standard RACF

commands. Assume that the troubled system is called PROD-A, and PROD-B has the possibility of sharing disks with PROD-A. In that case, the alternative recovery scenario involves the following steps:

1. Mount the volume with the RACF database of PROD-B on the PROD-A system.
2. Ensure that the RACF database of PROD-B has a different name than that of PROD-A. You might need to rename the database.
3. Issue the B8RACF command for the PROD-B RACF database,
4. Issue the corrective commands and exit B8RACF.
5. Ensure that the RACF database has the proper name for usage on PROD-B. You might need to rename the database.
6. Ensure that the volume is mounted on PROD-B, and IPL PROD-B.

The scenario is less complex and requires less seldom used skills (like use of stand-alone utilities, and multistep RVARY sequences).

Note: An important restriction for this use of is that **all** RACF databases must be primary databases, and that active backup databases are **not** supported. So, after successful recovery of the primary RACF database, copy the primary database over the backup database. Alternatively, you can use to reissue the same recovery commands again to the backup copy of the RACF database.

RACF database switching using RVARY

This section shows the sequence of RVARY and RENAME commands that are used to inactivate the System RACF database, and to activate an Offline RACF database. The advantage of this approach is that executing tasks on the system are not interrupted. However, it is only possible to use these steps if the two RACF databases are sufficiently alike. For instance, the USERID and current GROUP of active tasks should exist in both the *current* System RACF database as well as the *new* System RACF database. If the two databases are dissimilar, results can be unpredictable. Suppose the current RACF databases are:

```
Primary:     SYS1.RACF.PRIM
Backup:      SYS1.RACF.BACK
```

Only one Offline RACF database exists:

```
Offline:     SYS1.RACF.OFFLINE
```

To inactivate the primary RACF database, you can issue the RVARY SWITCH command. This switches the function of the primary RACF database to the backup; the primary database is deactivated. This results in the following situation:

```
Primary:     SYS1.RACF.BACK
Backup:      unused
Offline:     SYS1.RACF.OFFLINE
Inactive:    SYS1.RACF.PRIM
```

The next step in the process involves the RENAME command to make the Offline RACF database take the place of the primary.

```
rename  SYS1.RACF.PRIM     SYS1.RACF.PRIM.SAVE
rename  SYS1.RACF.OFFLINE  SYS1.RACF.PRIM
```

Now, the next set of RVARY commands can be issued to activate the PRIM (ex-OFFLINE) database.

```
rvary  ACTIVE DATASET(SYS1.RACF.PRIM)
rvary  SWITCH
```

The result of the last set of commands is that the PRIM (ex-OFFLINE) database is first activated as the backup database, and then switched to become the primary database. The BACK database, which was in the primary position is inactivated. At this moment the OFFLINE database has become the active primary database.

```
Primary:     SYS1.RACF.PRIM (ex-OFFLINE)
Backup:      unused
Inactive:    SYS1.RACF.PRIM.SAVE
             SYS1.RACF.BACK
```

If you want to create a backup database for the new PRIM database, you should allocate a data set of appropriate size, and run and IRRUT200 or IRRUT400 job. To prevent data loss, rename the existing BACK data set to BACK.SAVE before creating the new BACK data set.

```
rename  SYS1.RACF.BACK     SYS1.RACF.BACK.SAVE
```

After the IRRUTxxx job to create the new BACK database, the situation is as follows:

```
Primary:     SYS1.RACF.PRIM (ex-OFFLINE)
Backup:      unused
Inactive:    SYS1.RACF.PRIM.SAVE
             SYS1.RACF.BACK.SAVE
             SYS1.RACF.BACK
```

The final command to activate the new BACK database is provided in the following example:

```
rvary  ACTIVE DATASET(SYS1.RACF.BACK)
```

resulting in:

```
Primary:     SYS1.RACF.PRIM (ex-OFFLINE)
Backup:      SYS1.RACF.BACK (copy of ex-OFFLINE)
Inactive:    SYS1.RACF.PRIM.SAVE
             SYS1.RACF.BACK.SAVE
```

RACF Offline commands

This chapter documents the RACF Offline commands and parameters. The main command B8RACF has two different types of subcommands. The first type consists of Control commands, the second type consists of the RACF and additional supporting commands.

The Control Commands can be used as part of the B8ROPT installation options module, or as part of the B8RPARM input file. When control commands are executed as part of the B8RPARM input file, authorization to execute the commands is verified using the authorization profiles described in “Security zSecure Admin RACF Offline authorizations” on page 620.

The RACF commands and additional supporting commands can be entered as part of the SYSTSIN stream. In an interactive TSO job, this input stream corresponds to the terminal. Because uses regular TSO services for obtaining command input, it is also possible to redirect command input using CLISTs and REXX execs for example.

The next sections describe the control commands, followed by the RACF and supporting commands.

The B8RACF command and Control commands

The environment is activated using the B8RACF command. This command does not accept any keywords or parameters. Instead, before setting up the environment, and prompting the terminal user for RACF commands, it processes several supporting commands from two different sources. The first set of commands comprises those commands that are set up during installation. These commands are located in the B8ROPT module. The second set of commands is retrieved from the B8RPARM DD-statement. The B8ROPT module is required, and must at a minimum specify the resource class used for profiles. After successful execution of the commands from both sources, the terminal user is prompted to enter RACF commands.

Control commands specified using B8ROPT and B8RPARM

This section describes the syntax and authorization requirements for the Control commands.

RACFDB
Specify the Offline RACF database.

LOGDS
Specify the LOG file.

SMF
Specify the SMF processing options.

END
End the Control commands.

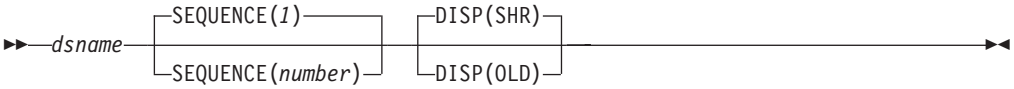
For information about reading the syntax diagrams, see Appendix A, “Reading Syntax Diagrams,” on page 1689.

Specifying the RACF database to be used

The following diagram describes the RACFDB command. The RACFDB command can be issued either as part of the B8ROPT module, as part of the B8RPARM input stream, or in the B8ROPTxx files. In the absence of any RACFDB commands, attempts to use the databases that are preallocated to ddnames INDD1 to INDD*n*.

If your RACF database is physically split into multiple databases, that the number of RACF databases used should match the number of databases specified in your System RACF database range table (ICHRRNG). Also, the System RACF database range table should specify the actual key ranges used for the Offline RACF databases.

RACFDB



The RACFDB command is used to specify which databases to use for this session. Because a RACF database can be physically split into multiple data sets, multiple RACFDB commands can be issued to specify all physical data sets. In that case you should also specify the sequence number. When specifying multiple RACFDB commands, specify the data sets in ascending sequence number order.

dsname
The *dsname* specifies the name of your Offline RACF database. Standard TSO

naming conventions apply. If the data set name does not start with your TSO prefix, enclose the data set name in single quotes unless your TSO profile is set to *noprefix*.

SEQUENCE(number)
The sequence number should match the relative data set number that is used in your RACF range table. If your RACF database is not physically split, you can omit the SEQUENCE keyword. In that case, the default (1) is used.

DISP(disp)
The default disposition of the data set is SHR. That means that other users can concurrently access the same Offline RACF database. Normal RACF serialization applies, so concurrent updates are possible without loss of database integrity. However, serialization does not guard against other types of access to the database. If you want to have exclusive access to this particular RACF database, you can also specify disposition OLD. Although the value NEW is accepted, it is currently ignored, and treated as SHR.

Specifying the LOG file to be used

The following diagram describes the LOGDS command. The LOGDS command can be issued either as part of the B8ROPT module, in the B8RPARM input stream, or in the B8ROPTxx files.

LOGDS

The LOGDS command is used to specify which LOG data set is to be used for this session.

dsname
The *dsname* specifies the name of your LOG data set. Standard TSO naming conventions apply. If the data set name does not start with your TSO prefix, enclose the data set name in single quotes unless your TSO profile has been set to noprefix.

The LOGDS command is intended to be used with the RACFDB command. When using the B8RVARY command to switch the Offline RACF database, you must also switch the corresponding LOG data set. By using this setup, the LOG data set contains all commands that have been issued against a particular Offline RACF database.

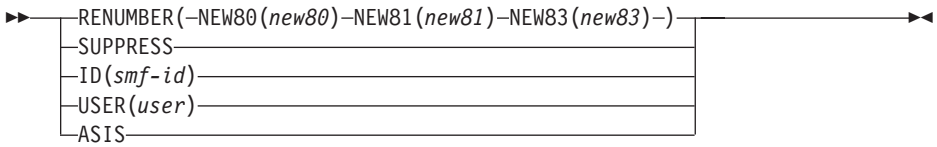
The B8REPLAY command uses the information in the B8ROPTxx file to select the LOG data set (command file) containing the commands to be issued.

Specify SMF processing options

Most of the standard RACF command processors write SMF records during processing. It is almost impossible to distinguish the SMF records written for an update to the Offline RACF database from those records written for an update to the active System RACF database. To enable identification, use the SMF command to mark SMF records as written during a session. Some of the command options apply to all SMF records, while others apply only to the RACF SMF records. The best option is to modify the SMF-ID for the affected records.

Note: See "Auditing" on page 603 for important prerequisites for SMF record processing.

SMF



The SMF command is used to specify how to handle the SMF records created while is active. Several possibilities are provided. To ensure that the relevant SMF records can be identified, include the SMF command in the B8ROPT installation options module. This way, the installation can ensure that the relevant SMF records can be identified. If you do not include the command in the B8ROPT installation options module, no SMF command is issued, and the default action is that all SMF records are left unmodified. This means that the records cannot be distinguished (other than by time of day) from those SMF records that are created as part of regular RACF commands that affect the active system RACF database.

RENUMBER
The renumber keyword indicates that you want the RACF SMF records to be assigned a different record type. The command has three subkeywords to specify the new record types for the three types of RACF SMF records.

NEW80(new80)
The *new80* variable specifies the new SMF record-type to assign the standard RACF type-80 SMF records, while is active. For best results, set this value to *180*.

NEW81(new81)
The *new81* variable specifies the new SMF record-type that is to be assigned to the standard RACF type-81 SMF records, while is active. For best results, set this value to *181*.

NEW83(new83)
The *new83* variable specifies the new SMF record-type that is to be assigned to the standard RACF type-83 SMF records, while is active. For best results, set this value to *183*.

SUPPRESS
The SUPRESS keyword indicates that all SMF records created while the keyword is active are suppressed. Use this option only when you are sure that the RACF commands issued will never affect a RACF database involved in production processes. Example of such usage would be a temporary database used for educational purposes.

ID(smf-id)
The ID keyword indicates that you want to assign a different SMF-ID (System-id) to those SMF records created while is active. The assignment of the new ID applies to all SMF-records. This is the best option to allow these records to be differentiated from records written when other databases are active. The resulting SMF records can be separated easily using the SID(smf-id) control statement for the IFASMFDP and IRRADU00 utilities for example.

USER(user)
Indicates that you want to assign a different USER(*SMF80UID*) value in the RACF command SMF records. The assignment of the new user value applies only to SMF record type 80. This field is usually empty unless the installation has

placed a specific value in the SMF Common Exit Parameter Area (CEPA) using the IEFUJI SMF exit. The value of this field is installation-specific and does not need to represent the RACF `userid`.

ASIS
The ASIS keyword indicates that you do not want to modify any SMF record created while RACF Offline is active. This means that all SMF records generated by the RACF commands for actions against the Offline RACF database cannot be distinguished from those against the System RACF database. Select this option if you are not concerned about any RACF command auditing. Using this keyword makes sense only for preparing or testing on a test partition.

Ending the Control commands

The following diagram describes the END command. The END command is required as the last command in the B8ROPT module. It can also be used to signal the end of the B8RPARM file. In the absence of the END command, processing of the Control commands continues to the end of the B8RPARM file. The EXIT command can be used as alternative to the END command. It performs identical functions.

END

As indicated in the preceding diagram, the END command does not have any keywords or parameters. It indicates the end of the input file.

RACF commands and supporting commands

After successful execution of the Control commands, the terminal user is prompted to enter RACF and supporting commands. These commands can be entered from the terminal, or are read from the SYSTSIN DD-statement when B8RACF is used in batch.

This section describes the syntax of the RACF and supporting commands. For information about reading the syntax diagrams, see Appendix A, “Reading Syntax Diagrams,” on page 1689.

RACF commands

RACF Offline supports most RACF commands in unmodified form. The RVARY, SETROPTS, and RACLINK commands are not supported. Also, RRSF support is explicitly disabled in RACF Offline. Do not use the AT or ONLYAT keywords, both are ignored. Irrespective of the system settings specified using the TARGET operator command, automatic command direction is not performed.

Supporting commands

In addition to the RACF commands, RACF Offline provides additional supporting commands. These commands are summarized in the following table.

Table 269. RACF Offline supporting commands

Command	Description
“**B8RACFLG**” on page 616	Manage the LOG file.
“**B8REPLAY**” on page 617	Reissue RACF commands from a LOG file.
“**B8RVARY**” on page 617	Switch and select Offline RACF database

Table 269. RACF Offline supporting commands (continued)

Command	Description
"**CKGRACF**" on page 618	Run the CKGRACF program.
"**END**" on page 618	End the session.
"**EXEC/EX**" on page 618	Run a REXX EXEC or TSO CLIST.
"**ISPF**" on page 619	Enter ISPF.
"**LOGON**" on page 619	Use authorization of user in Offline RACF database.
"**PROFILE**" on page 620	The TSO PROFILE command.
"**REPORT**" on page 620	Report RACF command usage.
"**TIME**" on page 620	The TSO TIME command.
"**TRACE**" on page 620	Invokes the RACTRACE command. Before using this command, you must install the RACTRACE function. For details, see "**TRACE**" on page 620.

The following sections provided more detailed information about the RACF Offline supporting commands. Commands are presented in alphabetical order.

B8RACFLG: The B8RACFLG command can be used to reset or list the name of the LOG file used to record all RACF commands issued against an Offline RACF database. This command is available in both the B8RACF and the ISPF environment. The command has the following syntax.

B8RACFLG

The B8RACFLG command accepts one keyword, which can have one of the following values.

Open
The OPEN keyword specifies that the LOG file is to be opened. This function is only available if the log data set has been specified using the LOGDS Control command.

Close
The CLOSE keyword specifies that the LOG file is to be closed. This function is only available if the log data set has been specified using the LOGDS Control command.

Reset
The RESET keyword specifies that the LOG file is to be reset. All information recorded up to that point will be overwritten with the new LOG of RACF commands issued.

Flush
The FLUSH keyword specifies that the LOG file is to be flushed. All buffers are written. The LOG file will continue to be used. This function is only available if the log data set has been specified using the LOGDS Control command.

List
The LIST keyword requests display of the data set name for the LOG file currently in use. Figure 477 shows an example of the output.

```
 B8R200A Enter RACF Command or "END"
b8racflg list
 B8R287I Current logfile is BCSC.RACFDS.B8RLOG
 B8R200A Enter RACF Command or "END"
```

Figure 477. B8RACFLG command List option output

B8REPLAY: The B8REPLAY command can be used to reissue the commands saved in a LOG file. The SELECT(xx) parameter on the B8REPLAY command identifies a pre-allocated B8ROPTxx file. That B8ROPTxx file is scanned for the LOGDS statement naming the LOG data set that is to be used. This command is available in both the B8RACF and the ISPF environment. The command has the following syntax:

B8REPLAY

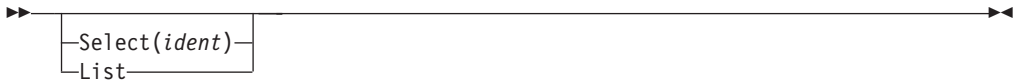
The following keywords and parameters can be used:

Select
The SELECT keyword specifies the B8ROPTxx DD-statement that contains Control commands. The last two characters of the DD-statement are provided by the *ident* value.

ident
The *ident* value is used as the last two characters of the B8ROPTxx DD-statement.

B8RVARY: The B8RVARY command can be used to switch and select the Offline RACF database that is used. It can be issued with a parameter to select a file containing RACFDB, LOGDS, and SMF commands. You can also issue B8RVARY without any parameters. In that case, the terminal user is prompted for confirmation and the Control commands. For the available Control commands, see section "The B8RACF command and Control commands" on page 612. This command is available in both the B8RACF and the ISPF environment. The command has the following syntax:

B8RVARY



The following keywords and parameters can be used:

Select
The SELECT keyword specifies the B8ROPTxx DD-statement that contains Control commands. The last two characters of the DD-statement are provided by the *ident* value.

ident
The *ident* value is used as the last two characters of the B8ROPTxx DD-statement.

List

The LIST keyword requests a display of the Offline RACF databases currently in use. Figure 478 shows an example of the output.

```
 B8R200A Enter RACF Command or "END"
b8rvary list
 B8R246I RACF databases in use
 B8R247I Number   Volume     Dataset
 B8R248I    1     BCSC02     BCSC.RACFDS
 B8R200A Enter RACF Command or "END"
```

Figure 478. B8RVARY command List option output

If you use B8RVARY without any keywords or parameters, an interactive switch of the Offline RACF database is assumed. You are prompted to confirm switching. Following confirmation, you are prompted for additional Control commands (RACFDB, LOGDS, and SMF). This allows for flexible selection of the desired databases and options. Terminate the prompting sequence with the END command.

```
 B8R200A Enter RACF Command or "END"
b8rvary
 B8R232A Confirm switching RACFDB (YES/NO)
yes
 B8R234A Enter B8RVARY subcommand or "END"
racfdb 'bcsc.racfds'
 B8R274I RACF DB to be used is BCSC.RACFDS
 B8R234A Enter B8RVARY subcommand or "END"
logds 'bcsc.racfds.b8rlog'
 B8R268I LOG data set to be used is BCSC.RACFDS.B8RLOG
 B8R234A Enter B8RVARY subcommand or "END"
end
 B8R200A Enter RACF Command or "END"
```

Figure 479. Using the B8RVARY command interactively

CKGRACF: This command invokes the CKGRACF command which allows management of USRDATA fields, other "difficult" fields. For more information on CKGRACF, see Chapter 14, “CKGRACF Command Language,” on page 1499. The authorization to use the CKGRACF functions is obtained from the Offline RACF database.

END: The END command is used to signal the end of the RACF command input stream. In the absence of the END command, processing of RACF commands continues to the end of the SYSTSIN input file. The EXIT command can be used as an alternative to the END command. It performs identical functions. This command is applicable only in the B8RACF environment.

END

The END command does not have any parameters.

EXEC/EX: Execute a REXX EXEC or TSO CLIST. The RACF commands in this file are executed against the Offline RACF database. This command is available in the B8RACF environment, as well as in the ISPF environment.

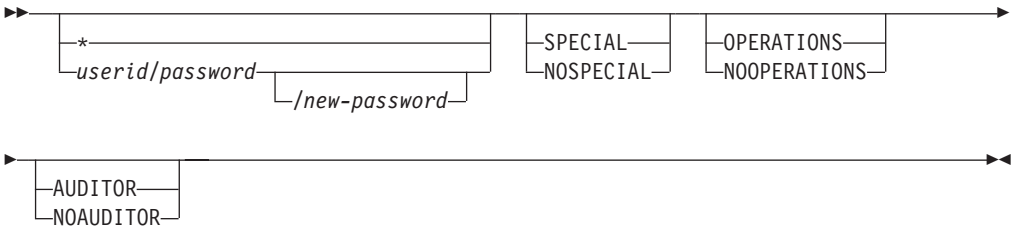
ISPF: This starts the ISPF full-screen environment. Most of the functions of ISPF use the System RACF database. If RACF commands are issued, using either option-6 or the RACF panels, the Offline RACF database is used. When leaving the ISPF full-screen environment, line-mode B8RACF resumes. This command is applicable only in the B8RACF environment.

ISPF

The ISPF supporting command for B8RACF accepts the same parameters and keywords as the TSO ISPF command. For more information on these parameters and keywords, see ISPF documentation or the ISPF HELP file.

LOGON: The LOGON command results in using the RACF authorizations of a user in the Offline RACF database. This command is applicable only in the B8RACF environment. The LOGON command has the following syntax:

LOGON



If you enter just the LOGON command without any parameters, the current `userid` is used to LOGON to the Offline RACF database. If you specify a *userid*, you must also specify the password of that userid. If you want to be prompted for the password in non-display mode, end the USERID with a forward slash (/).

If you specify the current password, you can also specify a new password. To be prompted for the new password in non-display mode, end the current password with a forward slash (/).

You can also explicitly specify that you want to logon using your current userid by using an asterisk (*). In that case, any password you specify is ignored.

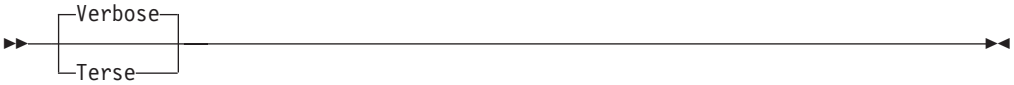
The optional attribute keywords (NO)SPECIAL, (NO)OPERATIONS, and (NO)AUDITOR request that the effective value of the specified attribute is temporarily set or reset after logging on to the Offline RACF database. The value of the attribute in the Offline RACF database itself is not changed. Use of these keywords requires access to the B8R.*attribute.master-racfdb-name* resource in the XFACILITY resource class in the System RACF database. For more information about the required authorization see “Command authorization verification” on page 621.

If you specify one of the optional attribute keywords, you also must specify a value for the userid, including the password, or use an asterisk to logon using your current userid. Password prompting in non-display mode is not supported when using an optional attribute keyword.

PROFILE: This command runs the regular TSO PROFILE command. It can be used for instance to specify the data set prefix or to specify that messages should include a message identifier, or that WTP messages should be shown on the terminal.

REPORT: The REPORT command can be used to print a summary of the RACF commands issued in the current session. The resulting display contains a header, a list of the supported RACF commands including the number of times that the command ended with a particular return code, and a *Total* line showing the total number of commands issued. This command is applicable only in the B8RACF environment.

REPORT



The REPORT command accepts one keyword, which can have the value Verbose or Terse.

Verbose
All supported RACF commands plus a Total line are listed in the command usage report.

Terse
Only those RACF commands that were issued, including a Total line are included in the command usage report. An example display is provided in the following example.

```
 B8R200A Enter RACF Command or "END"
report terse
 B8R450I Command      #rc0     #rc4     #rc8
 B8R451I ALTUSER         1        0        0
 B8R451I LISTUSER        1        0        0
 B8R452I Total           2        0        0
 B8R200A Enter RACF Command or "END"
```

Figure 480. REPORT command Terse option display

TIME: This command runs the regular TSO TIME command.

TRACE: The TRACE command invokes the RACTRACE function that provides Write To Operator (WTO) trace messages of the RACROUTE calls issued by most applications. Before using this command, you must install the RACTRACE function in the appropriate system libraries. You can download this function from the RACF Downloads site accessible at http://www-03.ibm.com/servers/eserver/zseries/zos/racf/goodies.html. The use of the RACTRACE function can result in large amounts of console and syslog messages and is not intended for use by regular users. The authorization to use the RACTRACE functions is obtained from the Offline RACF database.

Security zSecure Admin RACF Offline authorizations

This chapter discusses the Security zSecure Admin RACF Offline resources used to verify authorization to use the B8RACF command and its control commands. When the commands are issued as part of the B8ROPT options module, no authorization check is performed. When the commands are executed as part of the

B8RPARM input file, the user must have sufficient authority to the specified resources. The resources should be covered by profiles in the resource class as specified in the B8ROPT installation options module. (XFACILIT is the default.) Generic profiles are permitted. For any resource that is not covered by a profile, the corresponding function is not permitted.

No matter how the Offline RACF database is specified (using either B8ROPT, B8RPARM, or preallocated), the user must always have UPDATE access to the resource described in "RACFDB." This is verified at the end of parameter processing.

Aside from the resources described in this section, the user should also have sufficient access to standard RACF resources, like UPDATE access to the selected RACF database.

Authorization to use RACF Offline

The authorization to use the B8RACF command, and therefore the authorization to use the Offline RACF environment as provided by Security zSecure Admin RACF Offline is controlled by the following resource.

B8R.RACF.OFFLINE. This resource controls usage of the B8RACF command. The user needs at least READ access to this resource.

Command authorization verification

Some Security zSecure Admin RACF Offline commands and their keywords are controlled using several resources. These resources are described in the following sections.

RACFDB

The RACFDB command has one major parameter: The name of the data set to be used as the Offline RACF database. When using the RACFDB command, the user must have UPDATE access to the resource. If the Offline RACF database is preallocated, Security zSecure Admin RACF Offline verifies the authority to use the allocated database using the same resource during initialization of the Offline RACF environment.

- **B8R.RACFDB.***dsname*

  This resource controls usage of `dsname` as an Offline RACF database. If the Offline RACF database is only used in a non-data sharing environment, the user needs at least UPDATE authority for this resource. If the Offline RACF database has indicators that it is used in a data sharing environment, the user needs at least CONTROL authority for this resource. If no covering profile has been defined, an error message is issued, and the selected database is *not* accepted. A generic profile can be used to protect this resource.

  In addition to this resource that describes the authority to use the selected data set as an Offline RACF database, the user also needs regular UPDATE access to use the selected data set.

SMF

Each of the major keywords of the SMF subcommand is protected by its own resource. If no covering profile has been defined for the specified keyword, the command is rejected.

- **B8R.SMF.ASIS**

  This resource controls use of the ASIS option of the SMF command. The user needs at least UPDATE authority to this resource.

- **B8R.SMF.SUPPRESS**

  This profile controls use of the SUPPRESS option of the SMF command. The user needs at least UPDATE authority to this resource.
- **B8R.SMF.RENUMBER**

  This resource controls use of the RENUMBER option of the SMF command. The user needs at least UPDATE authority to this resource.
- **B8R.SMF.ID**

  This resource controls use of the ID option of the SMF command. The user needs at least UPDATE authority to this profile.
- **B8R.SMF.USER**

  This resource controls use of the USER option of the SMF command. The user needs at least UPDATE authority to this resource.

LOGON

Use of the optional attribute keywords on the LOGON command requires authorization. The following resources are verified:

- B8R.SPECIAL.*master-racfdb-name*
- B8R.OPERATIONS.*master-racfdb-name*
- B8R.AUDITOR.*master-racfdb-name*

The *master-racfdb-name* is the name of the first or only RACF database used in the RACF Offline session. If your RACF database is physically split, it is the database allocated with sequence number 1. If your RACF database is not physically split, it is just the name of the RACF database. An example resource name is

```
B8R.SPECIAL.SYS1.RACFDS
```

The required access level is UPDATE. If you have insufficient access, or if no profile is found, an ICH408I violation message is issued by RACF, an error message is issued by RACF Offline, and the effective value of the requested attribute is not changed.

Chapter 9. Merge Usage Guide

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•			

Use the Security zSecure MERGE command to merge RACF databases from multiple systems or to prepare for the RACF Remote Sharing Facility (RRSF). The `MERGE` operation analyzes RACF databases and creates the commands required for merging the data. You can use the MERGE command in combination with other zSecure functions to simplify operations like the following:

- List and compare multiple RACF databases (either from different system images, or the same system image at different times).
- Identify differences between databases on different systems.
- Synchronize databases.
- Merge one database into another while resolving definition conflicts.
- Rename profiles.

In order to synchronize data from different RACF databases, you must perform the following tasks:

- Collect profile data from multiple RACF databases.
- Analyze the data to determine the content differences between databases.
- Run RACF commands to reconcile the differences in data.

Security zSecure helps you perform these steps. The program reads profiles from different databases, compares the profiles, and produces reports for identifying differences in the data. It also creates the RACF commands required to merge the data. You can analyze the reports and the RACF commands generated before running the commands. You can also modify the commands if necessary. When you finish your analysis, you can run the RACF commands to merge the information from the source database into the current database. This process relies on the following commands:

- The `SUMMARY` command compares the databases and list the differences.
- The `MERGE` command generates the commands to merge database content and synchronize the data.

For information more information about merging RACF database content, see the following topics:

Listing and comparing profiles from more than one RACF database

Security zSecure uses the live RACF database or the data sources specified on the Setup - Files panel (option **SE.1**).

The CARLa command for reading from a RACF database or unload copies of the database is ALLOCATE (ALLOC). Because the RACF database does not contain system identification, you must include the COMPLEX keyword on the ALLOC command to specify an identifier for each database. The COMPLEX value is a one- to eight-character name required to distinguish which complex the records were read from. The following CARLa commands identify data sets from two different systems:

```
ALLOC DSN='SYS1.ZSECUR.SYSA.UNLOAD' TYPE=UNLOAD COMPLEX=ALPHA
ALLOC DSN='SYS1.ZSECUR.SYSB.UNLOAD' TYPE=UNLOAD COMPLEX=BRAVO
```

You can create these statements using either of the following methods:

- Generate them automatically based on the set of input files selected, including the COMPLEX assigned to the input data sets.
- Use the Command option (**CO.C**) to run the commands yourself.
- Specify the statements in the SYSIN statement of a batch job.

List profiles from both systems

Use the SELECT and LIST commands to list the profiles from both systems as shown in the following example.

```
NEWLIST TYPE=RACF TITLE='SYS1 profiles from both systems'
  SELECT CLASS=DATASET SEG=BASE QUAL=SYS1 COMPLEX=(ALPHA,BRAVO)
  SORTLIST KEY COMPLEX UACC ACL
```

Running this command produces the following results:

```
P R O F I L E   L I S T I N G    1 Aug 1996 06:30
SYS1 profiles from both systems

Profile key         Complex  UACC    User     Access  ACL Id
SYS1.*.**           BRAVO    NONE    IBMUSER  ALTER   IBMUSER
SYS1.**             ALPHA    NONE
SYS1.**             BRAVO    NONE    IBMUSER  ALTER   IBMUSER
SYS1.**.VTAMLST     ALPHA    NONE    -group-  UPDATE  SYSBASE
                                     -group-  UPDATE  SYSNET
SYS1.**.VTAMLST     BRAVO    NONE    -group-  UPDATE  SYSBASE
                                     -group-  UPDATE  SYSNET
                                     SYSCNM   READ    SYSCNM
```

```
P R O F I L E   L I S T I N G   12 Jun 2010 21:38
SYS1 PROFILES FROM BOTH SYSTEMS

Profile key         Complex  UACC    User     Access  ACL id   When
AMVQRK01.191        ZVICOM53 NONE    AMVQRK01 ALTER   AMVQRK01
AMVQRK02.191        ZVICOM53 NONE    AMVQRK02 ALTER   AMVQRK02
AMVQRK03.191        ZVICOM53 NONE    AMVQRK03 ALTER   AMVQRK03
AMVQRK04.191        ZVICOM53 NONE    AMVQRK04 ALTER   AMVQRK04
AFEROIE.191         PTHVM8   NONE    AFEROIE  ALTER   AFEROIE
                                     MAINT    ALTER   MAINT
ATIGTEL.191         PTHVM8   READ    ATIGTEL  ALTER   ATIGTEL
                                     MAINT    CONTROL MAINT
                                     -group-  READ    FAULTTXT
ATIGTEL.192         PTHVM8   READ    ATIGTEL  ALTER   ATIGTEL
                                     MAINT    CONTROL MAINT
                                     ATIGTE2  CONTROL ATIGTE2
```

Determining which system contains a profile

Use the SUMMARY command to determine the system that a profile comes from as shown in the following example:

```
NEWLIST TYPE=RACF TITLE='SYS1 profiles from both systems'
  DEFINE INA BOOLEAN WHERE COMPLEX=ALPHA
  DEFINE INB BOOLEAN WHERE COMPLEX=BRAVO
  SELECT CLASS=DATASET SEGMENT=BASE QUAL=SYS1 COMPLEX=(ALPHA,BRAVO)
  SUMMARY KEY INA INB
```

Running this command produces the following results:

```
P R O F I L E   L I S T I N G    1 Aug 1996 06:30
SYS1 profiles from both systems

Profile key                    INA INB
SYS1.*.**                      No  Yes
SYS1.**                        Yes Yes
SYS1.**.VTAMLST                Yes Yes
```

This report does not show each profile record, but only one line for each profile key and the indication which profiles exist in database *ALPHA*, *BRAVO* or both.

Locating profiles that exist only on one system

You can adapt the SUMMARY command to find profiles that exist only on one system. To list this information, you specify commands to count the profiles located for each profile key value and only list the key value if less than two profiles have this key. The following code sample shows how to locate these profiles.

```
NEWLIST TYPE=RACF TITLE='SYS1 profiles from both systems'
  DEFINE INA BOOLEAN WHERE COMPLEX=ALPHA
  DEFINE INB BOOLEAN WHERE COMPLEX=BRAVO
  SELECT CLASS=DATASET SEGMENT=BASE QUAL=SYS1 COMPLEX=(ALPHA,BRAVO)
  SUMMARY KEY INA INB COUNT(NONDISPLAY,<2)
```

Running this command produces the following results, which show only profiles that are on one system:

```
P R O F I L E   L I S T I N G    1 Aug 1996 06:30
Profile differences between two systems

Profile key                    INA INB
SYS1.*.**                      No  Yes
SYS1.TEST.**                   Yes No
```

Listing and comparing profiles from a current and an old database

Whenever a job fails, end users are quick to blame RACF. The most frequent question is: "What was changed since the last time I ran this job?" With a few simple CARLa statements, Security zSecure shows which profiles were added or deleted.

By allocating multiple RACF data sources from the same system, you can determine which profiles were added to the system as shown in the following example.

This example is based on the following configuration:

- A GDG of unloaded databases created on a daily basis
- Label the two most recent unloaded databases as OLD and CURRENT.

By allocating multiple RACF data sources from the same system, you can determine which profiles were added to the system as shown in the following example. To accomplish this task, use a current copy of the UNLOAD file or create one. Then, restore from backup an UNLOAD file from a time suitable for determining any changes.

The following CARLa commands list profiles from both databases:

```
ALLOC DSN='SYS1.ZSECUR.UNLOAD(-1)' TYPE=UNLOAD COMPLEX=OLD
ALLOC DSN='SYS1.ZSECUR.UNLOAD(0)' TYPE=UNLOAD COMPLEX=CURRENT

NEWLIST TYPE=RACF TITLE='SYS1 profiles yesterday and today'
  SELECT CLASS=DATASET SEG=BASE QUAL=SYS1 COMPLEX=(OLD,CURRENT)
  SORTLIST KEY COMPLEX UACC ACL
```

Running this command produces the following results:

```
P R O F I L E   L I S T I N G    1 Aug 1996 06:30
SYS1 profiles yesterday and today

Profile key         Complex  UACC    User     Access  ACL Id
SYS1.*.**           CURRENT  NONE    IBMUSER  ALTER   IBMUSER
SYS1.**             OLD      NONE
SYS1.**             CURRENT  NONE    IBMUSER  ALTER   IBMUSER
SYS1.**.VTAMLST     OLD      NONE    -group-  UPDATE  SYSBASE
                                     -group-  UPDATE  SYSNET
SYS1.**.VTAMLST     CURRENT  NONE    -group-  UPDATE  SYSBASE
                                     -group-  UPDATE  SYSNET
                                     SYSCNM   READ    SYSCNM
```

The SUMMARY command identifies profiles added or deleted since yesterday by requesting those profiles that only exist in one database:

```
NEWLIST TYPE=RACF TITLE='Profiles added and deleted'
  DEFINE ADDED('Add',HDR$BLANK) BOOLEAN WHERE COMPLEX=CURRENT
  DEFINE DELETED('Del',HDR$BLANK) BOOLEAN WHERE COMPLEX=OLD
  SELECT SEGMENT=BASE COMPLEX=(OLD,CURRENT)
  SUMMARY CLASS KEY ADDED DELETED COUNT(NONDISPLAY,<2)
```

Running this command produces the following results:

```
P R O F I L E   L I S T I N G    1 Aug 1996 06:30
Profiles added and deleted

Class    Profile key        Add  Del
DATASET  NEWUSER.**         Add
DATASET  SYS1.*.**          Add
DATASET  SYS1.TEST.**            Del
TAPEVOL  006269             Add
TAPEVOL  006765             Add
USER     NEWUSER            Add
P R O F I L E   L I S T I N G   28 Apr 2010 05:48
PROFILES ADDED AND DELETED

Class    Profile key          ADD DEL
ACCTNUM  FAKECDT.ACCTNUM.126  ADD
APPCLU   FAKECDT.APPCLU.118   ADD
APPCSERV FAKECDT.APPCSERV.84  ADD
SURROGAT LOGONBY.CHKQUEUE     DEL
USER     CHKQUEUE             ADD
USER     CRMBKW1              ADD
VMBATCH  FAKE015              ADD
```

You can use the SORTLIST and SUMMARY commands to combine the profile results from up to 32 complexes.

Merging a database

The MERGE command compares two systems and generates RACF commands to add and modify profiles on one of the systems. The MERGE command is available under zSecure Admin and Audit and zSecure Admin. It does not work if you only use zSecure Audit.

The MERGE command uses a current or main database (CURRENT or MAIN) and a source database (MERGESOURCE or MERGE. The current database receives the profiles copied from the source database. Usually the MERGE command runs on the system with the current database and source database is an unloaded RACF database from another (remote) system.

The merge process produces a list of RACF commands in the CKRCMD file. These commands perform add, delete, and modify actions to merge the content from the source database into the current databases so the databases are approximately the same. You can allocate separate files for different types of commands using the FUNCTION parameter on the ALLOC statement. This parameter specifies what type of commands are written to the file:

TYPE=CKRCMD FUNCTION=MAIN
If this function is specified, the CKRCMD file receives commands that can be run on the system with the current database. This file mostly contains the commands that *add* profiles and entries to the database.

TYPE=CKRCMD FUNCTION=MERGE
Receives commands that can be run on the system with the source database (MERGESOURCE). This file mostly contains the commands to *delete* all profiles are already present in the current system or profiles that were successfully merged. Use the MERGE function to *move* profiles between databases.

If you are not interested in the commands generated to one or both files, you can leave out the ALLOC commands. If no ALLOC command is specified, the program issues the CKR0696 message which you can ignore.

The following sample shows the basic commands to run the MERGE process:

```
ALLOC DSN='SYS1.ZSECUR.SYSA.UNLOAD' TYPE=UNLOAD FUNCTION=MAIN
ALLOC DSN='SYS1.ZSECUR.SYSB.UNLOAD' TYPE=UNLOAD FUNCTION=MERGE
ALLOC DD=CKRCMD TYPE=CKRCMD FUNCTION=MAIN
MERGE
ENDMERGE
```

Running these commands generates RACF commands in the file CKRCMD to add all users, groups, and applications that are currently defined on *SYSB* into *SYSA*.

Because the SETUP application does not support the FUNCTION parameter, you must enter ALLOC commands for the FUNCTION=MERGE data sets using the Security zSecure Command option **CO.C** or in the SYSIN of a batch job.

Note: You cannot MERGE databases accessed by the zSecure network. However, you can MERGE remote UNLOAD files.

Because MERGE uses a lot of virtual storage, it is more efficient to run this function primarily using batch jobs. To create the batch job, do the following:

1. From the Main menu, select the Command option (**CO.C** to open the Command panel.
2. In the entry fields, type the allocation commands for the merge process:

```
ALLOC DSN='SYS1.ZSECUR.SYSA.UNLOAD' TYPE=UNLOAD FUNCTION=MAIN
ALLOC DSN='SYS1.ZSECUR.SYSB.UNLOAD' TYPE=UNLOAD FUNCTION=MERGE
ALLOC DD=CKRCMD TYPE=CKRCMD FUNCTION=MAIN
MERGE
ENDMERGE
```

3. Type SUBMIT on the command line to generate the batch job.
4. From the SUBMIT option panel, you can edit and create the batch job:
   - Select option 2 to edit the generated JCL.
   - Type CREATE on the command line. Then, press **Enter** to save the JCL to an existing work data set.
5. Use the program you created as the base for creating the MERGE batch application.

Note: Member C2RJMALL in the SCKRSAMP library contains the basic MERGE commands. This job is documented in "IBM Security zSecure jobs" on page 699.

Cleaning up security databases

The MERGE command does not run successfully if either of the RACF databases has any serious internal inconsistencies. To start with clean data, run the VERIFY PERMIT,CONNECT command on each database. Then, run the commands generated by the VERIFY operation to clean up the database.

VERIFY PERMIT, CONNECT checks each database for references to undefined IDs, such as groups and user IDs on access lists or in OWNER or NOTIFY fields. These orphaned IDs are caused when IDs are removed from the RACF database without first running IRRUT100. Using Security zSecure to manage your RACF database prevents such inconsistencies.

Resolving inconsistencies

Performing a merge usually results in messages detailing inconsistencies between the two databases. You can use the following information to resolve inconsistence and differences in the databases.

Because conflicts are likely between the two databases, MERGERULE commands are placed between the MERGE and ENDMERGE commands. These rules specify which profiles have precedence. For example, to ensure that profiles in current database have precedence over profiles in the source database specify the following statement:

```
MERGERULE DEFAULT AUTHORITY=CURRENT
```

The current database value is used whenever a user authority differs from the source database. This simplistic approach can cause failed jobs due to insufficient authority. To prevent this problem, you can specify a statement that assigns the higher authority level to an ID that has different values in the current and source databases:

```
MERGERULE DEFAULT AUTHORITY=HIGH
```

For example, if this statement is present, the merge process assigns the UPDATE access to a user ID when the same user has READ access in one system and UPDATE access in the other.

You can specify the MERGERULE command for each user or group in the source database.

```
MERGERULE SOURCEID=PROD AUTHORITY=HIGH
MERGERULE SOURCEID=TEST AUTHORITY=LOW
```

If no MERGERULE applies to an ID, any conflicts in authority for the ID are flagged in the SYSPRINT. You must resolve any conflicts before the commands are generated.

You can use the following statement to specify authority per general resource class:

```
MERGERULE SOURCECLASS=FACILITY AUTHORITY=HIGH
```

Profiles also contain informational fields which can be useful for reporting. You can control the content merging for these fields using the following statement:

```
MERGERULE DEFAULT DATA=CURRENT
```

This statement indicates that the contents of fields in the current database are to be kept even if the contents are different from the source database. This processing applies to fields like the default group, programmer name, and installation data as well as the TSO segment.

If you do not specify MERGERULE commands, Security zSecure flags discrepancies in authority and incompatible data fields and stops processing.

Selecting profiles

Specify SELECT commands in the MERGE-ENDMERGE block to identify those IDs from the source database that must be copied into the current database. Only fields in the BASE segments of all profile classes are available for selection processing. The non-BASE segments like the CICS, DFP, and TSO application segments are automatically copied without any selection. This behavior means that these application segments are automatically processed during the merge, but it also means that you cannot use the existence of a segment as a selection criterion for all CICS or TSO users.

The following code sample shows how to copy the group *PROD* and all its user IDs:

```
MERGE
  SELECT CLASS=GROUP KEY=PROD
  SELECT CLASS=USER OWNER=PROD
  SELECT CLASS=(DATASET,GENERAL),
         (OWNER=PROD OR OWNER:OWNER=PROD OR QUAL=PROD)
ENDMERGE
```

These normal CARLa SELECT commands:

1. Select the group *PROD*, and all users who are directly owned by *PROD*.
2. Select all data set and general resource profiles with the following characteristics:
   - owned directly or indirectly by *PROD*
   - have a dsname that starts with *PROD*

The same techniques used in your CARLa reports work here.

Running these commands only generates commands to connect the users it copied to the group *PROD*. To connect the *PROD* users to all of the groups that they were connected to when the groups exist in the current database, add the following MERGERULE command:

```
MERGERULE DEFAULT CONNECT=IFUSER
```

This command copies all *connects* for users that were selected in the MERGE block. This merge rule is only an appropriate choice when identically named groups in the current and source database have the same function.

Renaming IDs

Use the MERGERULE RENAME operand to generate new users and groups in the current database with the same characteristics as an ID in the source database. Using this operand helps when different naming conventions are used in each of the two databases and profile names must be converted during the database merge.

Renaming can also be helpful when two groups have the same name but perform different functions in each database.

If you only want to copy and rename a single group, you can specify a SELECT and a MERGERULE RENAME command:

```
MERGE
  SELECT KEY=PROD
  MERGERULE SOURCEID=PROD RENAME=APPL
  MERGERULE DEFAULT AUTHORITY=MERGESOURCE DATA=MERGESOURCE
  MERGERULE DEFAULT CONNECT=IFUSER
ENDMERGE
```

When you allocate the same RACF data source as CURRENT and MERGESOURCE, you can rename a group or users within your current database.

Merging groups

You can use the MERGERULE RENAME operand to merge a group into an existing group. This is achieved by excluding the target group from the MERGESOURCE and renaming the source group as shown in the following example:

```
MERGE
  EXCLUDE KEY=APPL
  MERGERULE SOURCEID=PROD RENAME=APPL
  MERGERULE DEFAULT AUTHORITY=MERGESOURCE DATA=MERGESOURCE
ENDMERGE
```

Running these statements generates the commands to add all users in *PROD* to *APPL* when they were not already connected.

When you allocate the same RACF data source as CURRENT and MERGESOURCE, you can merge a group within your current database.

Note: Member C2RJMGRP in the SCKRSAMP library demonstrates this technique. This job is documented in "IBM Security zSecure jobs" on page 699.

Synchronizing passwords

Merge generates CKGRACF commands to set some statistical fields. This functionality can be useful for password synchronization because the commands generated can prevent users from being unduly revoked for inactivity. These commands are created when CKGRACF=YES is specified, which is the default setting. The following guidelines determine how the fields are set by the merge process:

- For a user ID that is present only in the source database, the merge creates a command to set the following fields for the user ID: `LJDATE`, `REVOKECT`, `PASSWORD`, and `PASSDATE`. These fields are set only if they are present.
- The `PASSWORD` is set even if the user ID is not set for password checking.
- If `LJDATE` is set, `LJTIME` is also set.
- If a user ID is present in both databases and the `PASSDATE` in the source database is the most recent one, a command is generated to set `PASSDATE` and `PASSWORD`. Otherwise, if the `PASSDATE` equals zero–indicating a password reset, the `LJDATE` determines whether a `PASSWORD` set command is created.
- If the `PASSWORD` is set for a user ID present in both databases, the command sets `REVOKECT` as well.
- If the `LJDATE` in the source database is the more recent, the command also sets the `LJDATE` and `LJTIME` values.
- CKGRACF commands to set `PASSWORD`, `REVOKECT` and `PASSDATE` are only generated if the zSecure data source is not an unload data set. If the data source is unloaded data, the commands cannot be generated to set password values because unload data does not contain passwords.

Important: If you want to merge password changes, verify that the current database and the source database use the same method for encrypting passwords. The merge process does not check the encryption. If the encryption method is not the same, users can end up with invalid passwords as a result of the merge.

Using MERGE to identify changes in RACF

When we interpret the current database as *yesterday's database* and the source as *today's database*, then `MERGE` can be used to generate commands to make yesterday's database look more like today's. Of course, any interval could be applied, a week or a month for example. zSecure provides the `C2RJMSYN` job to perform the process of merging changes from the current database back to the old database. For information about this procedure and other zSecure jobs and procedures, see Chapter 11, "Calling zSecure," on page 689. The process is complicated because the merge process does not generate both RACF commands to delete profiles from a database and RACF commands to add profiles to that database at the same time.

Note: Like other merge applications, the reporting application also requires that both databases are internally consistent. Security zSecure provides the tools to fix internal problems in a RACF database and maintain consistency between the databases. See "Resolving inconsistencies" on page 628.

You can also use the MERGE NEWLIST function to create custom reports for the MERGE function. You can use this feature to produce regular reports of all changes made to the RACF database or to produce reports on specific profiles if you are trying to understand and document the decisions made during merge processing.

The following code produces a report that shows all fields changes where the current value is different than the source value value or where either value is missing. For every change, the resulting report shows the profile, the field name, the old value and the new value.

```
newlist type=merge title='Fields changed'
  s exists(field) and (cur_value<<>>src_value,
                       or (missing(cur_value) and exists(src_value)),
                       or (exists(cur_value) and missing(src_value)))
  sortlist class profile(26) field,
         cur_value("Old value") src_value("New value")
```

Running this code produces the following results:

```
 D A T A B A S E   M E R G E   R E P O R T    1 Feb 1998 15:33
FIELDS CHANGED

Class    Profile                  Field    OLD VALUE         NEW VALUE
DATASET  C##A.A.*.TEXT            ACL                        C##B(READ)
DATASET  C##A.A.*.TEXT            ACL                        C##CSEL(READ)
DATASET  C##A.A.*.TEXT            ACL      C##A(ALTER)       C##A(READ)
DATASET  C##A.A.*.TEXT            ACL      C##AINT(ALTER)    C##AINT(READ)
DATASET  C##A.A.*.TEXT            ACL      C##BERT(ALTER)    C##BERT(READ)
DATASET  C##A.A.*.TEXT            OWNER    C##B              C##A
```

Note: Member C2RJMDIF in the SCKRSAMP library demonstrates this technique. This job is documented in "IBM Security zSecure jobs" on page 699.

Background

The Security zSecure data base merge functions can be used to merge two RACF data bases. The basic description of a data base merge is as follows:

- The process uses two RACF databases, a source database (SOURCE) and a current database (CURRENT).
- Both databases are read. Selected profiles from the source database are created on the current database.
- You can specify rules to indicate how to resolve problems that occur during merge processing due to differences in the definitions in the two databases.
- The results of the merge process are found in the merge reports and the CKRCMD file that contains the generated RACF commands and optional CKGRACF commands.

  You must always allocate the CKRCMD file for running the commands on the system for the current database. The RACF commands recreate the selected profiles that were copied from the source database.

  The optional MERGE reports describe the decisions made during the merge process. You can customize these reports for your environment.

For more information about how merge processing works, see the following topics:

- "The merge process"
- "The decision-making process" on page 633
- "RACF command processing order in MERGE commands" on page 634

The merge process

This topic describes the implementation of the merge process, in so far as is required to understand the merge in/out commands and merge results. It can be skipped safely when you are reading this manual for the first time.

The merge process is split into a number of successive steps. Each step must succeed for the next step to be run. The MERGE steps are:

1. Check for SETROPTS conflicts.

   The SETROPTS settings for both data bases are compared. If conflicts exist that make it impossible to transfer profiles, the merge process stops.
2. Check for user/group conflicts, check commands.

   During this step, the selected user and group IDs from the source data base are checked against the current data base. The MERGE commands are verified with the data base contents.
3. Determine superior groups.

   During this step, the new superior group for each group transferred or merged is determined.
4. Determine ownership for users and groups.

   During this step, the new owner for each user/group transferred or merged is determined.
5. Merge user-group connections.

   During this step, the new user-group connections and the connect attributes (such as group-special) are determined.
6. Determine default groups.

   During this step, the new default-group for each user is determined.
7. Determine owners for data set profiles and general resource profiles.

   During this step, the owner for each profile is determined.
8. Copy/merge ACL entries of data set and general resource profiles.

   During this step, the profile access lists are merged.
9. Merge remaining user/group/data set/general resource profile attributes.

   During this step, a decision is made on how to copy all other attributes. The decisions are made separately for security-related attributes and non-security-related attributes.
10. Generate RACF commands.

The decision-making process

During each step, the merge process compares selected source profiles with the current data base and tries to resolve any differences. The `MERGERULE` statements specified in the input commands help resolve errors or conflicts in the merge processing. The processing for security-related fields is different from the processing for non-security related fields. Whenever a decision must be made, the following guidelines are used to determine how to merge content:

1. Check for a specific `MERGERULE` command for this profile.

   When determining superior groups in step 3, a `MERGERULE SUPGROUP` command for this group is honored.
2. For security-related fields, check for a `MERGERULE AUTHORITY` command for this profile.

   When a user has a `group-SPECIAL` attribute on the source system but not on the current system, the presence of a `MERGERULE AUTHORITY(SOURCE)` statement for the user determines that the source attribute value `group-SPECIAL` is assigned to the user after the merge.
3. For security-related fields, check for a global `MERGERULE AUTHORITY` command.

   When a user has a `group-SPECIAL` attribute on the source system but not on the current system and no `MERGERULE AUTHORITY` was specified for the user or

group, the presence of a global MERGERULE AUTHORITY(CURRENT) statement determines that the user is not group-SPECIAL after the merge.

4. For non-security (data) fields, check for a MERGERULE DATA command for this profile.

   When a data set profile has owner GROUP1 on the source system and owner GROUP2 on the current system, the presence of a MERGERULE DATA(CURRENT) statement for the high-level qualifier of the data set profile determines that the owner is GROUP2 after the merge.

5. For non-security (data) fields, check for a global MERGERULE DATA command.

   When a data set profile has owner GROUP1 on the source system and owner GROUP2 on the current system and no MERGERULE DATA was specified for the high-level qualifier, a global MERGERULE DATA(SOURCE) would determine that the owner is GROUP1 after the merge.

6. Check for a built-in fallback.

   This check is highly dependent on the merge step. In most cases, this system selects a reasonable default.

7. If all else fails, issue an error message.

RACF command processing order in MERGE commands

The data base merge functions create commands in the following order:

1. Create or change profiles in the SECDATA and SECLABEL classes. These profiles include: Security level, security category, and security-label related profiles.
2. Generate all groups, top-down. For groups owned by a user that does not yet exist, IBMUSER is used temporarily. The owner is corrected in the processing for step 4.
3. Generate all users, in any order. For profiles owned by a user ID that does not exist, IBMUSER is used temporarily. The user is corrected in the processing for step 4.
4. Fix-up the owners for the groups, and users. Assign the correct user for users and groups that use IBMUSER.
5. Create and alter user group connections.
6. Change default groups for existing users, where necessary.
7. Create and alter general resource profiles in the PROGRAM, JESINPUT, APPCPORT, CONSOLE, TERMINAL, and TAPEVOL classes. After these have been defined, conditional access list entries and TVTOC entries can be created.
8. Create and alter data set profiles. After each ADDSD or ALTDSD action, PERMIT commands are issued to create or alter the access list and conditional access list.
9. Create and alter general resource profiles. After each RDEFINE or RALTER action, PERMIT commands are issued to create or alter the access list and conditional access list.

Frequently Asked Questions

For more information about the merge process, see the following topics:

1. “Which users and groups are merged?” on page 635
2. “Who performs the merge?” on page 635
3. “How do renames work?” on page 635
4. “What is DATA and AUTHORITY?” on page 636
5. “How do I check the results?” on page 636

Which users and groups are merged?

The merge process uses SELECT and EXCLUDE statements within the MERGE/ENDMERGE block to select profiles from the source data base. All selected profiles are merged with the current data base. The following processing behavior applies to SELECT commands:

- If no SELECT statement is specified, all profiles are selected.
- Non-RDS CONNECT profiles are selected automatically; the SELECT and EXCLUDE commands are not applied to these profiles.
- For an RDS, profiles are selected if their BASE segment is selected. If you select using fields from non-base segments, selection does not work.

Merging profiles does not always generate RACF commands. For example, no RACF command is created if group SYSCTLG is identical in the source and current data bases.

Who performs the merge?

Any user who has unrestricted access to the source and current data base or unload files can perform the database merge using Security zSecure. The product generates commands that are user-independent.

A system SPECIAL user with the AUDITOR attribute must run the resulting commands because audit attributes are also set. The RACF commands generated by the merge remove the user ID that generated the merge commands from the profiles and access lists created, where appropriate. This step prevents unintended ALTER access list entries.

How do renames work?

Within the MERGE/ENDMERGE block, you can specify MERGERULE SOURCEID RENAME statements. These statements cause a specific high-level qualifier to be renamed. This topic explains how that works.

Each user or group ID for which a RENAME is specified is merged using the new name. In all places where the source database is compared to the current database, the renamed value of the source ID is used. For example, if you rename the source ID CICSUSER to DB2USER, the merge process always compares the source ID CICSUSER to the current ID DB2USER. This value is used even if the current data base contains an ID called CICSUSER. If source group CICSGRP has owner CICSUSER, the merge process merges the group as if the owner was DB2USER.

The rename action applies in the following contexts

- The user or group ID.
- All data set profiles with a high-level qualifier equal to the specified ID.
- All references to the user or group ID: user-group connections, superior groups, subgroups, default-groups, owners, access list entries, notify fields.

The following restrictions apply to rename actions:

- Renames do not apply to general-resource profile names in the current release. They do apply to access list entries of these profiles.
- The merge process requires a one-to-one correspondence of source and current IDs. This requirement means that if you rename a source ID to a name existing in the current database, the latter ID might not be selected to be merged. Similarly, you cannot rename two source IDs to the same name during one merge run.

What is DATA and AUTHORITY?

Use the MERGERULE commands to specify DATA and AUTHORITY rules. Use the following rule of thumb to clarify when DATA applies and when AUTHORITY applies.

> If a field has values that can be compared as high and low (including some lists) and the settings are used for RACF, then AUTHORITY applies. Otherwise, DATA applies.

For example, if a field has text values like `OWNER` or `SUPGROUP`, the choice is typically between the source value and the current value, so DATA applies. If a field has numeric or logical values, but it is used for an external product like TSO region size, DATA applies.

AUTHORITY applies to RACF-specific logical values as described in Table 270.

Table 270. Use of AUTHORITY setting in merge processing

Field	Description
Access lists	The AUTHORITY setting determines both which access list entries are merged, and the access value used.
Connect attributes	The AUTHORITY setting determines the values of the following connect-attributes: • Authority, `JOIN` or `USE` for example • UACC • Group attributes: group-special, group-operations, group-auditor, group-ADSP, group-GRPACC, and group-revoke status.
Other attributes	The AUTHORITY settings is used for the special, operations, and auditor attributes; the revoke status; the UACC; and the security level.

How do I check the results?

The results of the merge process consist of RACF commands in the `CKRCMD` files and merge reports (`MERGE NEWLIST`).

You can check how a specific profile is processed by browsing the `CKRCMD` file which contains the RACF commands for altering the profile.

If your merge results look strange or cause undesirable effects in the RACF database, you can review the merge reports. These reports provide information about what commands were generated and run during merge processing. The reports can help you understand the decisions made for each profile. You can use the SELECT command to filter the merge reports to review data for specific resources. The following list presents some of the `SELECT` options that are useful for researching specific profiles:

- Use the SRC_PROFILE, CUR_PROFILE, and PROFILE fields for selecting specific profiles.
- Use the PASS and FIELD fields for selecting information about decisions made during a specific pass or for a specific field.
- The SRC_VALUE, CUR_VALUE, and NEW_VALUE fields describe what happened to the values for a specific field. You can pinpoint when changes were made by using the field-field compare operators, SRC_VALUE==NEW_VALUE or CUR_VALUE<<>>NEW_VALUE, for example.

For more information about the SELECT statement and options, see "MERGE: RACF Database Merge" on page 1101

How do I fix errors?

During the merge process, you can encounter two types of problems:

- Errors generated during the merge process, which cause the merge to stop.
- Undesirable results after merging the databases.

You can resolve both types of problems by adding or changing the MERGERULE commands.

For errors during the merge process, study the error message and the *IBM Security zSecure: Messages Guide*. These errors typically occur when the merge process has no value at all or cannot choose between two values, two owners for example.

You can resolve conflicts between two values by adding a MERGERULE DATA or a MERGERULE AUTHORITY command. To apply these commands to one or more specific profiles, specify a MERGERULE SOURCEID or MERGERULE SOURCECLASS. To apply a default for all profiles, use a MERGERULE DEFAULT command.

If no value can be found, either specify a superior group or owner using a MERGERULE SOURCEID command, or add to the SELECT statements to include the required values in the selection for merging.

If you get undesirable results, study the merge reports to see why the merge process made the undesirable decisions. The merge report tells you what type of command caused the decision. Typically, the command that caused the problem is one of the following:

- A local OWNER/SUPGROUP command. The decision was exactly what you specified using a MERGERULE SOURCEID command. Alter the command to suit your needs.
- A local DATA/AUTHORITY command. The decision was caused by a MERGERULE SOURCEID command that applies to the profile. Alter the command as required.
- A global DATA/AUTHORITY command. The decision was caused by a MERGERULE DEFAULT command that applies as a fall-back to all profiles. You can alter the default to suit your needs; or add a MERGERULE SOURCEID for a specific group of profiles that need non-default handling.
- A built-in command. This command is a built-in fallback used in case of errors, conflicts, or lack of commands. MERGERULE commands have precedence over built-in rules; by specifying such a command, you can alter the decision to suit your needs.

How are access lists merged?

When a profile is present in both databases, merging the access list (ACL) is fairly straightforward. However, if a profile is present in only one of the databases, some preliminary work is required before merging the databases. If the merge is done without doing this work, some user IDs end up without access to a given resource because the resource is protected by a different profile after the merge.

If a profile is present only on the source database, merge processing searches for the *equivalent profile* in the current database. An equivalent profile is one that protects the same data sets or general resources as the source profile. When the merge is processed, the source file is created on the current system and added to the access list of the equivalent profile. In effect, the merge is adding a redundant profile to the current system. If a profile is present only on the current system, but it is affected by the merge, a similar process is used to add a redundant profile to the source system. No profiles are actually added to the source database. Merge just functions as though they were.

Table 271 shows examples of merge processing results for profiles that are only present in one of the databases being merged.

Table 271. Examples of merge processing for profiles that are not found in both databases

Source	Current	Action
`A.B.**` with ACL `X,Y,Z`	A.** with ACL W,X,Z	Profile A.B.** is added to the current database, with IDs W, X and Z on the access list.
`C.**` with ACL X,Y,Z	C.D.** with ACL W,X,Z	Profile C.D.** is added to the source database, with IDs X, Y and Z on the access list.

This process cannot always be followed. The other database does not always have an equivalent profile that protects all the relevant resources. In this situation, the profile is added as-is and the access list is processed based on the following guidelines.

Access list processing uses the `AUTHORITY` setting and checks it against user and group IDs to determine how to merge the access list entries. Entries are processed based on the following general rules:

- Access list entries that are only present on the source profile are copied as they are with the following exceptions:
  - Entries with a LOW authority are skipped.
  - Entries with a SOURCE or CURRENT authority where the profiles selected for merging do not include the user or group are skipped.
- All other access list entries are processed according to the following rules.
  - Entries with SOURCE authority use the source value.
  - Entries with CURRENT authority use the current value.
  - Entries with LOW authority use the lowest access level of the two assigned values.
  - Entries with HIGH authority use the highest access level of the two assigned values.

The process for evaluating and merging the access list entries depends on evaluating the AUTHORITY setting and checking user and group IDs.

Evaluating the AUTHORITY setting

Access lists and conditional access lists for data set and general resource profiles are merged according to the AUTHORITY setting applied to the profile.

- For data set profiles with a MERGERULE SOURCEID AUTHORITY setting for the high-level qualifier, the merge uses the specified AUTHORITY.
- For general resource profiles with a MERGERULE SOURCECLASS AUTHORITY setting for the class, merge uses the specified AUTHORITY setting.
- In all other cases, merge uses a MERGERULE GLOBAL AUTHORITY setting.

Roughly speaking, the meaning of the AUTHORITY setting can be interpreted as follows:

Table 272. AUTHORITY setting

Authority setting	Meaning
SOURCE	Implies that no applications from the source system fail after the merge.
CURRENT	Implies that all applications on the current system continue running after the merge.
HIGH	Implies that all applications continue to work after the merge.
LOW	Is a restrictive setting that only grants access if both databases agree on the level. In general, this setting requires you to determine which additional PERMITs are necessary after the merge. Then, you must add them manually.

Checking the user and group ID

For each source access list entry, the merge checks whether the ID is present on the current data base. This process takes MERGERULE SOURCEID RENAME commands into account and also handles the special IDs `*`, `&RACUID`, and `&RACGPID`.

If an ID is not present in the current data base, and is not merged, the access list entry is skipped. For all other cases, the access list entries are selected according to the rules listed in Table 273.

Table 273. Access list selection rules for merging profiles

Source vs Current	Authority	Action
source-only	SOURCE	Add entry to access list if ID selected
	CURRENT	Add entry to access list if ID selected
	HIGH	Add entry to access list
	LOW	Do not add entry to access list
source access < current access	SOURCE	Use source (lower) access
	CURRENT	Use current (higher) access
	HIGH	Use higher (current) access
	LOW	Use lower (source) access
source access = current access	*any*	Keep access list entry as it is
source access > current access	SOURCE	Use source (higher) access

Table 273. Access list selection rules for merging profiles (continued)

Source vs Current	Authority	Action
	CURRENT	Use current (lower) access
	HIGH	Use higher (source) access
	LOW	Use lower (current) access

Notes:

1. If an access list contains an undefined ID, warning message `CKR0679` is issued. If you see this message, clean up the database using VERIFY PERMIT before performing merge processing.
2. If a user or group is not selected to be merged but is already present in the current data base, an access list entry for that ID can be merged.

How are connects merged?

User group connections are not merged by using a SELECT statement. Instead, a MERGERULE CONNECT statement determines which user group connections are to be merged. When a connection is selected to be merged, MERGERULE DATA and MERGERULE AUTHORITY commands determine how. The following processing behavior determines how to process connections during merge processing:

- A user group connection can be merged if both the user and the group are present on the current system or are present after the merge.
- When a user group connection is checked to see if it must be merged, the merge checks the CONNECT setting. The setting is checked for the user, the group, and the default setting in that order. If no CONNECT setting is present for the user, or if the user is not selected, the group setting is checked. If no CONNECT setting is present for the group, or the group is not selected, the global setting is used.
- Finally, if a user is selected, the connection to the default-group is always copied if this default-group is available after the merge.

The following process describes how the merge decision is made in different situations:

1. If the user is selected and has a CONNECT setting, the connection is used as follows:

   NONE
   Connect not copied

   IFUSER, IFANY
   Connect copied

   IFGROUP, IFBOTH
   Connect copied if group is selected; else go on to step 2
2. If the group is selected and has a CONNECT setting, the setting is used as follows:

   NONE
   Connect not copied

   IFGROUP, IFANY
   Connect copied

   IFUSER, IFBOTH
   Connect copied if user is selected; else go on to step 3

3. If the selection includes the user, the group, or both, use the default CONNECT as follows:

   NONE
   Connect not copied

   IFANY
   Connect copied

   IFUSER
   Connect copied if user is selected

   IFGROUP
   Connect copied if group is selected

   IFBOTH
   Connect copied if both user and group are selected

After a user group connection has been selected to be merged, it must be decided how the connect is to be used. The decision is made based on a MERGERULE AUTHORITY command. Once again, the MERGERULE commands are checked for the user, the group, and the default, in that order. The merge decision is made based on the following processing rules:

1. If the user is selected, and a MERGERULE SOURCEID AUTHORITY is present for the user, that authority is used. Else, go on to step 2.
2. If the group is selected, and a MERGERULE SOURCEID AUTHORITY is present for the group, that authority is used. Else, go on to step 3.
3. If a MERGERULE DEFAULT AUTHORITY is present, that authority is used. Else, issue an error.

The authority found (`LOW`, `HIGH`, `SOURCE`, or `CURRENT`) is then applied to the connect-attributes.

How do I exclude a user or group?

If you do not want to merge a user or group, specify an `EXCLUDE` command for the user within the MERGE/ENDMERGE block. Alternatively, you can create a `SELECT` command that does not include the user or group. For example, the following example shows the code required to merge the entire data base except for the group *NOTTHIS*:

```
merge
 exclude class=group key=notthis
endmerge
```

The user or group ID might still show up in the commands generated in the following situations:

- The ID might occur in the `PERMIT` commands to add the user or group to access lists. This occurrence only happens if the ID exists in the current data base and the `AUTHORITY` setting is not `LOW`. To prevent this error, specify the AUTHORITY(LOW) attribute.
- The ID might be used for creating a user-group connection in CONNECT commands. This occurrence only happens if the following conditions are true:
  - The ID exists in the current data base
  - The other side of the user group connection is being merged with a `CONNECT` value other than `IFBOTH` or `NONE`.

  To prevent the IDs from showing up set the connect attribute to CONNECT(IFBOTH).

- The ID might be used as owner, default-group, etc. if it exists in the current data base; the merge process may then use it as a fall-back value. To avoid this, assign another ID as owner or superior group (using the MERGERULE SOURCEID OWNER and SUPGROUP commands), or change the DATA and AUTHORITY settings to alter the decisions made by the merge process.

How are general resource classes merged?

A general resource class is not merged if it is not defined in the Class Descriptor Table (CDT) of the current system. It is not merged because you cannot add profiles in a non-existing class to the RACF database.

A common use of merge is to combine databases at different release levels during an OS upgrade. If you have RACF databases on different release levels and intend to merge them, perform the merge on the higher level system. During merge processing, the generated commands are to add profiles in the newer general resource classes. For the merge process, use a database copy of the lower-level database instead of an unload version which uses the CDT of the lower-level system.

If a general resource class exists on the target system, but is inactive, profiles are merged normally. The merge process generates SETROPTS CLASSACT and SETROPTS GENERIC commands whenever necessary.

Chapter 10. RACF Access Monitor

The RACF Access Monitor function provides RACF administrators with the data required to remove unused or obsolete resource profiles and authorizations defined within profiles. RACF administrators and analysts can also use this function to test resource profiles and access rights by running simulations against a candidate RACF database. The candidate database can be one prepared using Security zSecure Admin RACF Offline, or a database on another z/OS system where you intend to host production processes.

Using the Access Monitor function, you can monitor access events and collect the data for reporting and analysis. From the reports, you can view and analyze the resource profile and access usage.

Note: Your installation must have the Access Monitor program for the z/OS system installed and configured before using the program. You must also have access to the data sets used to consolidate the access data. For details on the setup and configuration, see *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

The RACF database cleanup function consists of three components:

- The RACF Access Monitor program (C2PACMON) used for data collection.
- The CKRCARLA program that summarizes and saves the collected data so it can be analyzed.
- An ISPF menu component that allows you to specify selection criteria for reports, generate reports, analyze reports, and perform RACF database cleanup tasks.

The following processes provide the data to analyze access events and perform RACF database cleanup tasks.

Data collection

The RACF Access Monitor program (C2PACMON) collects the usage data on resource profiles and the authorizations defined within the profiles. To collect the required RACF information, the function dynamically defines several RACF exits to capture RACF events and collect the required information. When the Access Monitor program is running, it monitors access on a continuous basis.

The collected Access Monitor records are saved to disk at the end of each SMF interval. The SMF interval is specified by using the INTVAL parameter in member SMFPRMxx in PARMLIB. The default INTVAL parameter value is 30 minutes. The CKRCARLA program is used to combine the collected records and write them to a data set. Each type of access event is saved in a corresponding access record.

Data consolidation

Because access monitoring runs continuously, it collects a large amount of data. To maintain a manageable amount of data for reporting, the Access Monitor process summarizes the data collected at each interval on a daily basis. The summary removes redundant profile information and provides access counts on profiles with multiple access events. The summarized data is written to a daily consolidation data set. Daily consolidation data sets can be further consolidated on a weekly or monthly basis using the CKRCARLA procedures provided with

zSecure Admin. Administrators can also create custom consolidation jobs to consolidate access data sets for different time intervals. For example, an installation might want to consolidate three monthly data sets into a single data set to generate quarterly Access Summary or RACF Usage reports. These consolidation data sets are the data source for the Access Monitor reporting functions.

Report Generation

Users process the consolidated access data by running ad-hoc queries to evaluate the profile usage and access data. Processing can be set up and run interactively using the options available on the Access Monitor menu in the product.

The access data can also be processed using CKRCARLA. Two CARLa `NEWLIST` types are available for this purpose. The first, `ACCESS NEWLIST` uses the Access Monitor records to report about the collected RACF events. The second, `RACF_ACCESS NEWLIST` shows profiles in the RACF database and annotates these profiles with usage data from the Access Monitor records.

With proper record selection through the user interface or a CARLa program, Access Monitor reports can include the profiles of interest for a particular application. For example, you can report on all access permitted by the Global Access Checking table. You can also create commands to delete profiles that have not been used recently.

Figure 481 on page 645 provides an overview of the Access Monitor data collection, consolidation, and reporting process. In the following figure, user requests for access are captured using RACF exits. Access data is collected by the RACF Access Monitor (C2PACMON) and saved to a daily consolidation data set. The daily files can also be consolidated into weekly or monthly collections, for example. The consolidated data sets are the data source for the CKRCARLA program used to analyze and report on the access information. You can also use data from the RACF database as the data source for the reporting process. You can specify the same database used when the access data was collected or a candidate database. Depending on the options you selected, report output can be viewed from printed reports or ISPF panel displays. The reports are generated using the CKRCARLA program.

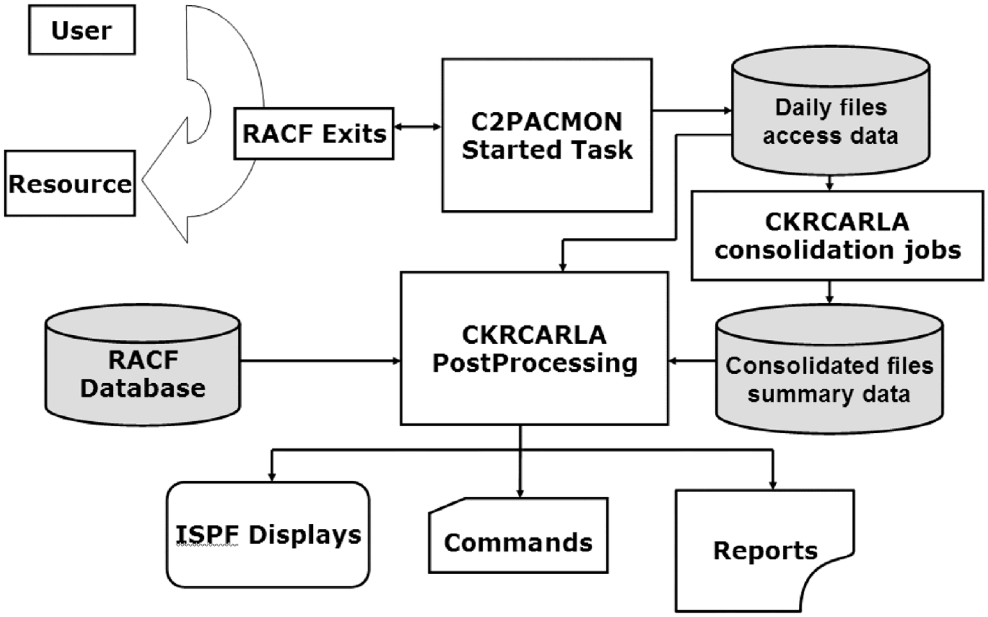


Figure 481. RACF Database Cleanup process program components and data flow

Collecting and consolidating data from the Access Monitor

The Access Monitor program runs as a started task. When the Access Monitor is running, it automatically collects access event data at a defined SMF interval (the default is 30 minutes) and writes event data to a data set. The SMF interval is defined by the INTVAL parameter in member SMFPRMxx in PARMLIB. The data collected for each event includes the following types of information:

- Resource name
- Profile name used
- Userid
- Jobname
- Port Of Entry (POE) information
- Access intent (READ, UPDATE, ALTER, and so on)
- Reason the access was granted
- Some attributes of the userid
- Date and time
- Number of events

Specifying Jobname and Port Of Entry collection

The Jobname and Port Of Entry information are present only if the Access Monitor task has been configured to collect that information. Collecting these fields makes consolidation less effective, so collect this information only insofar as you need it:

- The primary use of the JOBNAME field is with shared userids, such as those used in some JOB scheduling implementations, or those used for started tasks.
- The primary use of the UTOKEN_POECLASS field is with events, where access is granted using the conditional access list, such as for resources in the OPERCMDS class.

The person who sets up the Access Monitor task also configures the Access Monitor task to collect Jobname and Port Of Entry information. Discuss with this person for which userids or resource classes you need Jobname and Port Of Entry information.

Note: For instructions for installing and configuring the Access Monitor program and starting the task, see the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

Daily collection and consolidation

At the end of the day, the collection data for each interval is consolidated into a daily data set. During the consolidation process, all records for similar events are combined and counted together. In the combined records, the date and time of the last occurrence for each event is kept. The date and time information about all previous occurrences is discarded. The summarized data is written to a consolidated daily Access Monitor data set, which is the data set most often used to generate reports.

The Access Monitor program automatically performs the daily consolidation process. Other consolidated Access Monitor data sets might be created depending on the procedures set up by the person who installed and deployed the Access Monitor. For example, the daily data sets might be consolidated into monthly data sets. Instructions for creating the consolidated Access Monitor data sets are provided in the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*. Users can also create their own Access Monitor data sets by consolidating existing data sets. See "Consolidating data collected by Access Monitor" on page 684.

Configuring Jobname and POE-data collection

If you require detail information about the jobname or the Port Of Entry (POE) for certain access monitor events, some configuration members must be changed to specify for which situations the information is collected. There are three configuration members involved. The person who does the installation and deployment can specify the data set name where these three members are located. By default, they are located in the general C2PACMON configuration data set, as specified in the C2PACPRM parameter.

- Collection of jobname information is controlled by the contents of the C2PAMJOB member. This member has a two column layout. An example is shown after this paragraph. The member name and the ruler line are not part of the member, but are shown here for clarity only. The ruler line highlights that the second column must start in position 10 of the record.

  ```
  C2PAMJOB
     ----+----1----+----2
     IBMUSER  YES
     C2PSUSER NO
  ```

  The first column contains a USERID for which jobname information is controlled. The second column can contain the value `YES` or any other value. Jobname information is collected only for those users for which the value `YES` has been specified. For users that are not included in the C2PAMJOB member, or that have any value other than `YES` specified, jobname information is not collected. Be sure that all information in this member is specified in uppercase.
- Collection of Port Of Entry information is controlled by the contents of the C2PAMRCL and C2PAMPCL members. These members each have a two column layout. Examples are shown after this paragraph. The member name and the

ruler line are not part of the member, but are shown here for clarity only. The ruler lines highlight that the second column must start in position 10 of the record.

```
C2PAMRCL
   ----+----1----+----2
   OPERCMDS YES
C2PAMPCL
   ----+----1----+----2
   CONSOLE  YES
   TERMINAL YES
```

The first column contains a resource class for which POE information is controlled. The second column can contain the value `YES` or any other value. The C2PAMRCL member specifies the resource class for which the access verification is done. This can be any RACF resource class, such as DATASET, FACILITY, or OPERCMDS. The C2PAMPCL member specifies the resource class (type) of the POE. The following POE classes are recognized: TERMINAL, CONSOLE, JESINPUT, APPCPORT, and SERVAUTH. POE information is collected only for those events for which the Resource class and the POE class both have the value `YES` specified. If either class specifies any other value, POE information is not collected for this Access Monitor event. Be sure that all information in these configuration members is specified in uppercase.

Updates to the three configuration members described here are effective for data collected after a restart of the C2PACMON started task or after the C2PACMON started task has done a consolidation run. For more information about restarting the C2PACMON started task, or the consolidation process as done by the C2PACMON started task, see the section about C2PACMON operator commands in the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

Setting up zSecure to analyze and report on Access Monitor data

The process to set up zSecure to analyze and report on access event information depends on what you want to accomplish. You can use this data for the following tasks.

- Review access data for a specific profile or set of profiles over a specific time period
- Analyze access data for RACF database cleanup (removing unused profiles and permissions)
- Prepare to move a production workload from one z/OS image to another z/OS image

The setup process for each task is the same. First, identify the data resources that provide the required access information. Then, use the Setup Input Files option (**SE.1**) to specify the selected data resources as the information source for the access event analysis and reporting processes.

Identifying data sources for the access information

Review access data from a specific time period

The Access Monitor consolidation data sets contain real-time access event information collected over varying time periods. Daily consolidation data sets provide information about the last access occurrence for each profile or profile group during a given day. Monthly consolidation data sets provide information about the last access occurrence for each profile or profile group during a given month.

To determine the first day a particular data set profile was used, choose a data source that includes the daily consolidation data sets for the time period you want to investigate. These data sets provide information about access events for each day within the time period covered by these data sets.

To determine whether a data set profile has been used within the last two months, use access data collected monthly as the data source. This information is available from monthly consolidation data sets. In this example, data set profiles that have not been used in the last two months are either absent from the access event data, or present with an old date and time information.

The person who configured the Access Monitor program can provide the names of the consolidation data sets for your site. You can also create customized consolidation data sets from the existing ones if you want to investigate a time period not covered by the existing data sets. For example, if you want annual data, you can consolidate the monthly consolidation data sets. See "Consolidating data collected by Access Monitor" on page 684.

Using the Access Monitor data to prepare for RACF database cleanup
RACF database cleanup allows you to remove unused profiles and permissions from the live RACF database. To get information about which resources to target for removal, designate the following data sets as Access Monitor data sources: the CKFREEZE data set and the RACF database from the same image where the Access Monitor records were created.

You can replace the (live or foreign) database by an UNLOAD data set to improve performance of the analysis and reporting functions. In most data centers, there is already an UNLOAD data set available that is refreshed daily. Ask your local administrator.

Using the Access Monitor data to prepare for moving a production workload from one z/OS image to another z/OS image
To use the Access Monitor information to prepare for moving a production workload from one z/OS image to another, designate the following Access Monitor data sources: the CKFREEZE data set and the RACF database from the image that is the candidate for running that production.

You can replace the (live or foreign) database by an UNLOAD data set to improve performance of the analysis and reporting functions. In most data centers, there is already an UNLOAD data set available that is refreshed daily. Ask your local administrator.

Defining the access information data sources

Use the Setup Input Files option (**SE.1**) to specify the data sets to use for analyzing and reporting on access event data.

You can add the required data sets to an existing input file set or create an input file set. An input file set is a collection of data sets or files to be used as a data source. The data set type for Access Monitor data sets is ACCESS. For details, see "SE.1 Setup - Input files" on page 1645.

After you have added the Access Monitor data sets and selected the input set, the data is available to zSecure. Use the Access Monitor menu options (**AM**) to generate reports, analyze access data, and perform RACF database cleanup tasks. For details, see the following sections.

- "Selecting and reporting using Access Monitor data sets" on page 649
- "Reporting on actual profile usage" on page 649
- "Comparing access results against another database" on page 656

- "Reporting on RACF Usage" on page 658
- "Performing RACF database cleanup tasks" on page 671
- "Consolidating data collected by Access Monitor" on page 684

Selecting and reporting using Access Monitor data sets

You can set up and generate Access Monitor reports from the Access Monitor menu. Figure 482 shows the menu which is displayed by entering the AM command in zSecure Admin.

```
   Menu         Options       Info    Commands     Setup
 ____________________________________________________________________________

                        zSecure Admin+Audit for RACF - Access
Option ===> ____________________________________________________________________

1      Access          Access summary by user or profile
2      Compare         Compare monitored access against current RACF database
3      Permit usage    Permit usage information for current RACF database
4      Connect usage   Connect usage information for current RACF database
5      Profile usage   Profile usage information for current RACF database
6      Member usage    Member usage information for current RACF database
7      Global usage    Global usage summary for current RACF database
8      Remove          Remove unused profiles and authorizations
9      Cleanup         Remove permits, dataset and general resource profiles
```

Figure 482. Access Monitor menu

Reporting on actual profile usage

The data collected by the RACF Access Monitor includes information about various aspects of the RACF access verification request and result processing. For example, the data includes information about the use of the Global Access Checking (GAC) table. The access data also provides detailed information about the use of discrete (data set) profiles. You can report on this data interactively using the **Access summary by user or profile** option (**AM.1**) available on the zSecure Admin main menu.

Note: You can also create reports using the `NEWLIST TYPE=ACCESS` statement in a batch job. For details, see "ACCESS: Access Monitor Records" on page 953.

Setting up the report

The Access Summary report is based on input collected by the Access Monitor program. The report uses the ACCESS data sets specified in SETUP FILES. This report does not include information from the specified RACF input source. It only shows the actual profile and access usage as recorded by the Access Monitor program. It does not show access groups or data for profiles that were not used during the access monitor data collection period.

To begin reporting on RACF access request activity for `userid`s or resource profiles, select option **AM.1** from the zSecure Admin main menu. This option opens the selection panel shown in Figure 483 on page 650.

```
                        zSecure Suite - Access - Access
Command ===> ____________________________________________________________

Show records that fit all of the following criteria:
Userid  . . . . . . . . ________  (userid or EGN mask)
Complex . . . . . . . . ________  (complex or EGN mask)
SAF resource class  . . ________  (class or EGN mask)
SAF resource name . . . ____________________________________________
RACF match on . . . . . ____________________________________________

Advanced selection criteria
_  Further selection                    _ Date selection

Output/run options
1  1. Summarize by userid      2. Summarize by member class and profile
 _  Show configured fields
 _  Print format          Customize title     Send as email
       Background run     Full page form
```

Figure 483. RACF Access Monitor - Selection panel to generate Access Summary report

Use this panel to specify the report selection criteria and the report output and run options. Report results are output to the ISPF display by default. If you want the results to be printed or sent using email, select the **Print format** option.

On the report selection panel, if you leave the selection criteria blank and press **Enter**, all Access Monitor event records are displayed.

For field help, position your cursor in the field, then press **F1**. For panel help, press **F1** from the command line.

Figure 483 shows the selection panel to set up the Access Summary report. Use this panel to specify the selection criteria and the output and run options to generate the report.

Specify selection criteria

Many access monitor records contain information about both the resource name specified by the application and the profile name used by RACF. Use the report selection criteria to specify the application resource name in the **SAF resource name** field and the RACF profile name in the **RACF match on** field. You can use regular pattern matching on both fields.

For the **RACF match on** value, you can specify a RACF profile name. The profile can be an individual profile or a member in a grouping-class profile.

Selecting on either field can be useful because the profile name might be absent from the access event data under some circumstances. For example, when data set access is permitted through the Global Access Checking (GAC) table, RACF does not use a real data set profile. Consequently, the profile field is empty but the resource name is present. In contrast, in the access monitor records for define/delete events, the resource name might be absent. For example, the resource name is absent for RACF commands where the user directly specifies a RACF profile and a resource name is not used.

Specify advanced selection criteria

Use the **Advanced selection criteria** to further narrow the selection criteria. If you choose one of these options, you are prompted to specify the criteria when you press **Enter** on the report selection panel. Figure 484 on page 651 shows the selection criteria available for the Further selection option.

```
                    zSecure Suite - Access - Further selection
 Command ===> ____________________________________________________________
 All access monitor records
 Specify further selection criteria:
Jobname . . . . . . . . . _____________________________(jobname or EGN mask)
Port Of Entry class . . . _____________________________ (class or EGN mask)
Port Of Entry . . . . . . _____________________________(POE or EGN mask)

Select access records(Y/N/blank)
 _  Use of commands to add/delete dataset and general resource profiles
 _  Use of global access checking table
 _  Use of discrete profiles               _  Access attempts undefined users
 _  System special authority used          _  User has special attribute
 _  Operations authority used              _  User has operations attribute
 _  Installation exit used

 Action against resource  Intended access          Result
 _   Define              _ __ 1. Read             _ Success
 _   Delete                   2. Update           _ No profile
 _   Addvol                   3. Control          _ Not authorized
 _   Chgvol                   4. Alter            _ Other
```

Figure 484. Access Summary report - Further selection criteria

If the option **Show configured fields** has been selected on Figure 483 on page 650, the top block of Figure 484 allows selection of fields: Jobname, Port of Entry class, and Port of Entry. These fields cannot be selected, and are reported as empty, unless C2PACMON has been configured to collect this information.

The two other parts of this selection panel are always available and allow selection of characteristics of the profile and the event or the user at the time of the event. For field descriptions, press F1 for help.

The **Use of global access checking table** option provides an overview of the actual usage of the global access checking (GAC) table. This report provides information that is difficult to obtain in any other way. The GAC report results show all access that was permitted because the resource matched a profile name in the global access checking table. In the Access Summary report, the information shown is centered around the resources that were accessed. The report does not include information about the actual GAC Table entries used - just that a GAC Table entry was used to grant access. In contrast, the Global Usage option **AM.7** provides a report on the use of the GAC Table. The AM.7 report is centered around the GAC Table and does not provide information about the actual resource or users that were permitted access.

If the Access Monitor data is collected on a z/OS V1.13 system or a z/OS system with PTFs UA61826 and UA61827 applied, the Access Monitor records include information about the authority used to allow access. The record also contains information from the ACEE about the current system level SPECIAL and OPERATIONS attributes of the user. Selection on the value N is only available if a CKFREEZE data set for the applicable system is allocated and if the CKFREEZE data set indicates that the required support is installed.

In the last selection block of Figure 484, you can specify selection criteria based on the following options.

- Use **Actions against a resource** criteria to select records based on the action taken during the event. For example, if you select Delete, the Access Summary report includes access records with information about delete profile actions.
- Use **Intended access** criteria to select records based on access level and an operator. For example, to include information about all access events where the

user requested Update access or higher, enter the > operator in the first field and 1 (Read access) for the Access level in the second field. To include information about access events where the user requested Read access, specify the = operator.

- Use the **Result** criteria to select records based on the outcome of an access event.

Figure 485 shows the advanced selection criteria available for the Date selection option which allows you to select records for a particular period.

```
                        zSecure Suite - Access - Date selection
Command ===>

Date selection
From date . . . . ________    Until date  . . . ________

Valid date formats are "01JAN2009", "2009-12-31", TODAY, or TODAY-nnn.
Specific dates entered on this panel are meaningful only if represented in the
set of Access Monitor input data sets. For additional information see HELP.
```

Figure 485. Access Summary report - Date selection criteria

Generate report output

The report output is organized based on the option selected in the **Summarize by** field.

- The **1. Userid** option generates a report in which the results are organized by `userid`. On reports shown on the screen, use the **S** command on any userid event entry to view more detailed information about the resource class and name. In a printed report, the resource class and resource name are shown at a secondary level.
- The **2. Member class and profile** option generates a report with the results organized by resource class and resource name with a secondary level for the `userid` information.

  The option name **Member class and profile** is used to emphasize that this value represents the resource class as used by the application.

If **Show configured fields** is selected, fields Jobname, POE, and POE class are available on the **Further selection** panel and are included in the generated reports. These fields are empty, unless C2PACMON has been configured to collect this information.

Summary results are shown on the ISPF screen by default. To generate a printed report, select the Print format options. For details on the Print option settings, press F1 for help.

Interpret the results

The information available in the access monitor event records is always shown in a summary format. This approach reflects the fact that the Access Monitor data sets used as a data source are always already a summary of multiple events. As mentioned in “Collecting and consolidating data from the Access Monitor” on page 645, the daily collection data sets provide a sequence of half-hour summaries of access event data. The daily consolidation data sets provide a single summary of 24 hours of access event data.

Figure 486 on page 653 shows an example of the Access Summary report results summarized by Userid.

Figure 486. Access summary report - Event overview by userid

Reviewing high-level access event information: Both the Access Summary report formats (**userid** and **member class and profile**) provide the same detail information. Only the hierarchy and the access counts shown on the intermediate summary levels are different. This example focuses on two types of information shown in reports. The number of times an access event occurred and the date and time of the first and last occurrence.

Occurrence fields

This number reports the total number of times that the events on this line occurred. For example, the entry for the `userid RCCSL01` in Figure 486 reports that this userid was used for 358 events.

```
__        358 RCCSL01  JOHN SMEDLINE SPEC.  13Mar2009 11:27 13Mar2009 11:30
```

To see more detail on these events, type **S** in the field for the entry to open the detail panel shown in Figure 487.

Figure 488. Access summary report - Event overview by resource class (profile)

You can then use the **S** command again to view details about the DATASET class resources. For example, selecting one of the DATASET class entries opens a panel where you can see additional information about the event such as the Profile key as shown in Figure 489.

First occurrence, Last occurrence fields

These fields report the first time the access event occurred and the last time the access event occurred in a given time period. The values in these fields depend on the type of consolidation data set used as data sources for the reports. The first occurrence shows the earliest date present in the data sources for the access time. As the section "Collecting and consolidating data from the Access Monitor" on page 645 explains, the meaning of the date value depends on the level of consolidation applied to the ACCESS data sets used as data sources. The First occurrence column indicates an approximate first use and has the precision of the consolidation period. If you are using consolidated weekly Access Monitor data sets, the **First occurrence** can only show the first week that access occurred.

Reviewing detailed event information: From the overview panels in the Access summary report, issue an **S** line command for any entry to view more detailed information about a particular event type. Figure 489 shows more information about the UPDATE requests from `userid` RCCSL01 including the resource class, resource name, and profile key used.

Figure 489. Access summary report - Event overview by resource (member) name

This panel shows the `userid` RCCSL01 issued 22 requests to UPDATE a resource over the given time period. In this example, the time period is one day. To compare this information against the current profile and access list definitions in the current RACF database, use option **AM.2**. A comparison can be useful to determine how a particular userid or resource has been affected by changes to the RACF database.

You can also use this panel to get detailed event information such as the access intent, the event result, and the resources used. For example, from the information shown in Figure 489 on page 654 you can gather the following information.

1. Userid `RCCSL01` issued 22 request to UPDATE a resource.
2. The request was permitted (return code, **AccRC**=`0`).
3. The UPDATE requests were for data set resources.
4. The resource that was updated was CRMBE01.C2PACMON.T#TIM.IOCONFIG, which was satisfied using profile CRMBE01.*.*.** .
5. This same event occurred twice during the measurement period, one quickly following the other on March 13th 2009.

This panel also shows the request and access flags in effect for **RGPCAVP** , **GUGSOPGX**, and **SO**. Table 274, Table 275, and Table 276 provide flag field descriptions.

Table 274. Access Summary report - RGPCAVP flag fields

Flag	Description
R	The RACF Indicator is on (Y) or off (N) or not specified (blank).
G	A generic profile is requested.
P	Return of a Private/CSA profile is requested.
C	This request is part of RACF command processing.
A	The DEFINE request performs an internal authorization check.
V	The DEFINE request only verifies authorization.
P	This request is the result of automatic propagation.

Table 275. Access Summary report - GUGSOPGX flag fields

Flag	Description
G	A generic profile is requested.
U	The requesting `userid` is not RACF defined.
G	An entry in the global access checking table was used.
S	System special authority used.
O	Operations authority used.
P	The requesting task is Privileged or Trusted.
G	Access requested for GROUP.
X	Installation exit used.

Table 276. Access Summary report - SO flag fields

Flag	Description
S	User's ACEE had the system-wide SPECIAL bit set at the time of the check.

Table 276. Access Summary report - SO flag fields (continued)

Flag	Description
O	User's ACEE had the system-wide OPERATIONS bit set at the time of the check.

Selecting the **Occurrence Timestamps** entries opens the access event record detail display as shown in Figure 490.

Comparing access results against another database

Using one of the advanced options of the Access monitor data analysis, you can also compare historical data against a current RACF database. This function is available from option **AM.2** in zSecure Admin. The current RACF database is the one that you have specified in SETUP, by default it is the current system RACF database.

Comparing the actual usage data against the RACF database can help verify that proposed changes to the RACF database do not negatively affect the production environment. For example, if a profile identified for removal was recently used to grant access to a resource, you can communicate with the users or groups that use the resource about the proposed change before putting it into production. You might also run a comparison to understand the effects of changing the RACF database in use or moving an application to another system.

If you prefer to run an Access monitor function using a batch job, use the NEWLIST TYPE=ACCESS statement with the SIM_* fields to perform a compare. Option AM.2 provides the following selection fields:

```
  Menu         Options       Info    Commands     Setup
 ──────────────────────────────────────────────────────────────────────────────

```

Figure 491. RACF Access Monitor - Access - Compare selection panel

The selection panel for option AM.2 provides many of the same selection criteria available for option AM.1. The additional selection options available are based on the **results** of comparing actual successful access events to access events that would be permitted using the selected RACF data source. The selected RACF data source is the one specified using the Setup Files option (SE.1). You can compare access based on the access result or based on the profile used for allowing or preventing access. The resulting reports all have a similar layout. Figure 492 shows an example of the report.

```

Figure 492. RACF Access Monitor - ACCESS summary simulated access is less report

In Figure 492 on page 657, the **AccRC** column shows the access that was historically permitted. The **SimRC** column shows the access that would be permitted using the current RACF data source. These differences might be caused by any of the following events:

- profile added or removed
- access list changed
- universal access changed
- warning mode changed
- use of operations or group-operations
- access through the special attribute

You can analyze the differences and check if these results are expected based on your selected RACF data source. Using the general selection criteria and the **summarize by** selection option, you can focus on the users or the resources that are important in your environment.

Reporting on RACF Usage

The Access Monitor data sets contain information collected by monitoring actual access attempts on the system. However, these data sets do not contain information about the resource profile definitions themselves. Also, the Access Monitor data sets cannot provide any information about profiles or access list entries that were not used. To report on all profiles and their information, you need data from the RACF database. Use Access monitor options AM.3 through AM.7 to generate reports that integrate information from the defined profiles in the RACF database with information about actual usage from the Access Monitor data sets.

Counting access events

To report on the use of all profiles and entries in the selected RACF data source, the usage information in the Access Monitor data sets needs to be matched to the correct profiles, Access List (ACL) entries and group connections. This matching process is not always straightforward. For example, in the RACF database, a data set profile for ABCD.** has an ACL with two groups and a single userid. The definition of the profile is:

```
DATASET Profile and ACL User profile

ABCD.**                 USER1
UACC    NONE             NAME     TEST USER1
USER1   READ             DFLTGRP  SYS1
GRP1    UPDATECONNECT    SYS1
GRP2    UPDATE
```

In this example, the request of USER1 to read data set ABCD.TEST is easily matched against profile ABCD.**, and it is easy to determine that the access list (ACL) entry used is the one for USER1 because this userid has specific READ access to the ACL. However, matching and counting access attempts is not always that easy. Consider another set of definitions like the previous example:

```
USER2
NAME        TEST USER2
DFLTGRP     SYS1
CONNECT     SYS1, GRP1, GRP2
```

If USER2 also tries to read data set ABCD.TEST, the ABCD.** profile clearly matches. However, how can you determine which ACL entry should be used? The USER2 ID is connected to two groups and both groups allow access.

zSecure Admin matches the access request for USER2 against both ACL entries. If there were a specific ACL entry for USER2, the access would be matched against that specific entry instead of the group entry. Just like RACF, zSecure Admin always uses the most specific entry for matching. In this case USER2 is not covered by a specific ACL entry. Consequently, for this access request zSecure Admin counts USER2 as having two matching entries: one because of membership in GRP1 and the other because of membership in GRP2.

zSecure Admin has a similar process to mark that a particular group-membership is used. For the first access request by `USER1`, no group-membership was used, so its group connection is not marked as used. For the second situation for `USER2`, both the group-connections to GRP1 and the GRP2 are marked as been used.

The matching of profiles to resource access requests becomes even more complicated for grouping resource classes. In the following example, you can get some idea of the complexity by looking at some CICS transaction profiles. Grouping class profiles RESGRP1 and RESGRP2 definitions both have as member the transaction CEMT with an ACL that contains USER1.

```
GCICSTRN RESGRP1       GCICSTRN RESGRP2
Member   CEMT          Member    CEMT
ACL      USER1  READ   ACL       USER1   READ
```

When CICS is started, the relevant resource classes are RACLISTed which loads all the relevant profiles into a dataspace and merges the grouping resource class profiles.

When USER1 runs the transaction CEMT two resource profiles grant access to USER1. Again, zSecure Admin matches the access against both profiles and both ACL entries. The result is that both profiles and both ACL entries are marked as used. Actual situations might be more complex. For example, you might have multiple profiles with different access lists that have both users and groups on the access list. Some situations might be more simple. For example, you might have two or more grouping profiles that do not cover any member resources.

The matching is done during the post-processing phase using the specified RACF data source. This information about groups, ACLs, and grouping resource profiles is not present in the Access Monitor data sets, but is the result of a simulation process. It can easily be repeated using the same Access Monitor data sets, but for a different RACF input source. The results of the matching and counting of access monitor events against the RACF profiles and information can be generated using the `RACF_ACCESS NEWLIST` that you implicitly use when you run one of the options **AM.3** to **AM.8**, available from the zSecure Admin main menu.

Creating RACF Usage reports using data from Access monitor and the RACF database

Use the RACF options (**AM.3 -AM.7**) to relate the ACL (permit), connect, and profile definitions in the current RACF database to the actual resource access events and profile usage recorded in the Access Monitor data sets. (shown in Figure 493 on page 660). This information can help you understand the impact of changing RACF database profiles and ACLs before moving the changes to production. You can also use the data to identify and investigate unused or obsolete profiles and authorizations.

```
 Menu         Options       Info    Commands     Setup
──────────────────────────────────────────────────────────────────────────────
                        zSecure Admin+Access for RACF - Access
Option ===> ____________________________________________________________________

9      Cleanup         Remove permits, dataset and general resource profiles
```

Figure 493. Access Monitor menu

You can specify the type of data source for the RACF Usage reports. The following options are available:

1. If you use data sources from both the RACF database and the Access Monitor program, the report provides information about actual use of both permits and connects.
2. If you only use the RACF database as a data source in combination with the SIMULATE RACF_ACCESS option, the report provides information about the permits and connects permitted based on the RACF database profile definitions. The output is an exploded view of all permits and connects defined in the RACF database, including the effects of RACLIST merge processing.

The information from the RACF data source is combined with the data from the Access Monitor data sets. The resulting report provides information about use of the profiles and information in these profiles. For example, a Permit Usage report can show that the access list for a resource profile in the RACF database allows UPDATE access to 10 different groups. But the Access monitor event data for the last six months shows that only one group has requested READ access to the resource.

Each record shown in the RACF Usage reports represents a single access list (ACL) entry. The reports also include special pseudo entries for the UACC and the high-level qualifier <HLQ> of the resource. Using separate records for each ACL entry makes it easy to process the information and present detail information about how often a particular ACL entry was involved in allowing or preventing access to the resource.

The process to set up the reports and analyze the information in the RACF usage reports is similar for all the Access monitor reports. This documentation illustrates the process using the RACF Permit Usage report. You can follow the same process for the other reports.

For more information about the RACF Access Usage reports including detailed field descriptions, see “RACF_ACCESS: Connects and permits” on page 1213.

Setting up and generating the reports

This procedure illustrates how to set up and generate the Permit usage report. You can use this same process to generate the other Access monitor reports. However, the entry fields and selection criteria are not the same for each report type.

The Permit usage report shows profiles and their ACL entries as defined in the RACF database combined with the relevant usage data from the Access Monitor

data sets. To begin reporting permit usage, select option **AM.3** from the zSecure Admin main menu to open the selection panel shown in the Figure 494.

```
 Menu         Options       Info    Commands     Setup
──────────────────────────────────────────────────────────────────────────────
              zSecure Admin+Audit for RACF - Access - Permit usage
Command ===> ____________________________________________________________

Show permits that fit all of the following criteria:
Permit id . . . . . . . ________  (permit id or EGN mask on access list)
Class . . . . . . . . . ________  (class or EGN mask)
RACF profile name . . . ________________________________________
Complex . . . . . . . . ________  (complex or EGN mask)
Show accesses . . . . . _  Non-zero counts     _  Zero counts

Profile to use  _  1. Use historic profile name in access summary if present
                   2. Simulate access in database to find current profile

_  Further selection                    _  Date selection

Output/run options
_  Print format          Customize title     Send as email
      Background run     Full page form
```

Figure 494. Access - Permit usage report

Use this panel to specify the report selection criteria and the report output and run options. Report results are output to the ISPF display by default. If you want the results to be printed or sent using email, select the Print format option.

To view all the profiles and ACL entries, leave the selection criteria blank. Then, press **Enter**.

For detailed field information about any panel, position your cursor in a field and press F1 to view the help. For panel help, position your cursor on the command line, then press F1.

Specify selection criteria:

Show permits that fit all the following criteria:
In these selection fields, you can use special values such as `-UACC-` and `-other-` as well as patterns to match the values for other selection criteria fields.

Show accesses
For this selection criteria, type an option number to base the record selection on ACL entries that are used (**non-zero counts**) or ones that are not used (**zero counts**).

Profile to use

Use this criteria to indicate whether reporting is based on profiles present in the Access Monitor data sets, or on the profiles as currently defined in the RACF data source.

1. The **1. Use historic profile name in access summary if present** option bases reporting on the profile used at the time of access checking. This profile is found in the Access Monitor data sets. Access requests that refer to a profile that still exists are counted in the typical way. Access requests that refer to an existing profile are counted in the normal way.

If that profile no longer exists, zSecure Admin does not match the access request to any real profile, but instead the access request is counted on dummy profile `<hlq>.**` for ACL entry `-other-`.

2. The **2. Simulate access in database to find current profile** option discards the profile recorded at the time of the access request. The resource name is used to locate the currently applicable resource profile. This operation is like a replay of the historic events against the current database.

Both these reporting options have their advantages. For example, if you are looking at the data from a usage perspective for data base cleanup purposes, select option 1, **1. Use historic profile name in access summary if present**. If you are evaluating the effectiveness of your current definitions, select option 2, **2. Simulate access in database to find current profile**. There is not much difference in the report output for these two options if no significant changes were made in the current RACF database since the time the access event data was recorded.

Specify advanced selection criteria: Use the **Advanced selection criteria** to further narrow the selection criteria. After selecting one of these options on the report selection panel, press enter to specify information for the selected criteria.

Use the **Further selection** option to specify criteria based on access request results, the profile or connect creation date, and the access level used in the access request. Figure 495 shows the selection criteria available for the Further selection option.

```
 Menu         Options       Info    Commands     Setup
_____________________________________________________________________________

               zSecure Admin+Audit for RACF - Access - Further selection

       4. Alter                 4. Alter              4. Alter
```

Figure 495. RACF Usage report - Further selection criteria

Selecting records based on Access request result

This option selects records based on the outcome of the access requests.

access allowed
The ACL entry grants access at the requested level and the Access Monitor data sets also recorded a successful access.

access prevented
The ACL entry denies access at the requested level, and the Access Monitor data sets also recorded a failed access.

unexplained
Category for all other access results. For example, events in the unexplained category include attempts where access should have been permitted based

on the ACL entry show up as failed attempts in Access Monitor data sets, or vice versa. The most common reasons for an access record to be included in the unexplained count are changes in the ACL, UACC, or (group-)operations attribute.

Each of these options requires two data points: The first field specifies an operator, the second field specifies a target number of occurrences. For example, use the `Access allowed` option to investigate successful access attempts. To find access events in which access was successfully permitted more than 100 times, type `>` in the first field and `100` in the second field.

Selecting records based on profile creation date

On the Further Selection panel for the Permit and Profile Usage reports, use the **creation date** option to select records based on the profile creation date. Unfortunately, you cannot select on ACL creation date because RACF does not record when an individual ACL entry was added or changed.

On the Further Selection panel for the Connect Usage report, the date selection criteria selects access event records based on the date the user was connected to the group.

Example

To avoid reporting permit usage for new profiles, you can specify an **Until** date of `today-nnn` to suppress all recently created resource profiles.

Selecting Access level usage

Use the access levels options to select records based on **Access allowed**, **Highest access used** and **Lowest violation created**. The lowest violation option selects records with the minimum access level that resulted in an access violation.

Each of these selection options requires an operator value and an access level setting. The operator field sets a threshold for selecting records based on access levels and outcomes. For example, in the first entry field for the **Access allowed** option, typing **1** in combination with the default operator selects all records with successful access attempts using READ access or higher.

For a list of operators, press F1 on the field to see the help.

Example

If your organization has a policy of allowing access to resources at the minimum level required, you can identify resource profiles with access levels higher than the minimum by specifying the **Access allowed** selection criteria in combination with the **Highest access used** option. The accesses shown in the resulting report can be used as target for a *use it or lose it* cleanup approach. To avoid populating the report with access events where users request access to their own resources such as user-dataset profiles, specify `<=alter` for the **Access allowed** criteria.

Selecting the advanced selection criteria **Date selection** option opens the panel shown in Figure 496 on page 664. Use this panel to specify record selection criteria for a particular period.

```
                        zSecure Suite - Access - Date selection
Command ===>

Date selection
From date . . . . ________    Until date  . . . ________

Valid date formats are "01JAN2009", "2009-12-31", TODAY, or TODAY-nnn.
Specific dates entered on this panel are meaningful only if represented in the
set of Access Monitor input data sets. For additional information see HELP.
```

Figure 496. Access Summary report - Date selection criteria

Specify report output options: Report results are output to the ISPF display by default. To print or email the report, select the **Print format** option and specify the options you want to use. Press F1 in any field to get help.

Reviewing report results

Figure 497 provides an example from the Member Usage report showing the first level results for all CICS-related resource classes.

```

```

Figure 498. RACLIST merged profile permits and UACC - Member profiles for selected Member class

In this detail view, you can see the individual member profiles. This information does not mean that the profiles are defined in the member class. These profiles can also be defined as members in a corresponding grouping class profile.

You can continue zooming in on report data to get details.

Reduced access information

In the Member profile detail view, the **Red** (Reduced Access) column indicates whether the access level shown for this userid or group is less than it would be if the specific ACL entry were absent. For example, the **Red** field contains `Yes` for an entry that shows a userid that was permitted READ access to a resource when the user also belongs to a group that has UPDATE access. In this example, the userid has the lower READ access because of the READ permit. If this ACL entry was removed, the user would have the higher UPDATE access based on the group membership.

```

******************************** Bottom of Data ******************
```

Figure 499. RACLIST merged profile permits and UACC report - Access list information for selected member profile

Notes on interpreting RACF Access Usage reports

- The `-UACC-` entry always has a high violation count. The high count is caused by the violations from all users that are not included on the access list or in any group on the access list. RACF first checks if the user has access to a resource by

checking the access list. If the access list does not allow or prevent access, RACF uses the UACC. Thus, the count on the -UACC- entry is typically rather high.

- Especially for the -UACC- entry, The report does not show the user or job that accessed or failed to access the resource. The fact that the UACC was used is an indicator that the user or group is not present on the access list. There is no option to zoom in to a level of detail that shows which user. If you need more information about this situation, set up an ACCESS report that selects the correct class and profile to show the users that accessed the resource.
- Some applications verify access to resources without actually using or accessing these resources. These access verifications are counted and reported in the RACF Usage reports. An example is an application that uses RACF access to determine the list of functions to be shown on a panel. The application performs this RACF access verification while suppressing all messages and auditing. After the user chooses an option, the application might do a second access check with auditing to record that the user has used the function. In contrast to SMF processing, the RACF Usage reports also include the initial verification process that is used to build the selection panel.
- Most reports include a column to indicate *reduced access*. This column indicates whether the access level shown for the userid or group is less than what it would be if the specific ACL entry were absent. For example, if a userid has been permitted READ access and at least one of the groups the userid is a member of has UPDATE access, the userid access reported is READ. However, if the specific permit for the userid is removed from the ACL, the access for the userid increases to UPDATE because of the group membership. In this example, the **Red** field for the entry where the READ access contains Yes to indicate that this permission represents reduced access.

Example: Reporting on Member usage

RACF administrators use RACF grouping resource classes and member lists because they allow a single access definition to be used for many different resources. These grouping resource profiles can include a long list of members. The members are used as if individual profiles had been defined in the corresponding non-grouping (or member) resource class. The use of grouping and member resource classes is described in the *RACF Security Server Administrator's Guide* (SA22-7683).

The use of grouping class profiles is transparent to the application that uses RACF functions to perform access verification. An application such as CICS or IMS checks access to the resource in the member class. For the entire process to work, the resource class must have been RACLISTed using either a SETROPTS RACLIST command, or by the application using a RACROUTE REQUEST=LIST statement. During the RACLIST process, information from the grouping class profiles and the member class profiles is merged. The application might have permitted access based on information coming from any of the profiles used during the merging. Consider this example where the following two grouping resource profiles have been defined:

```
GCICSTRN RESGRP1              GCICSTRN RESGRP2
Member CEMT                   Member CEMT
UACC   NONE                    UACC   NONE
ACL    USER1 READ             ACL    USER1 READ
                                     GRP1  READ
```

The userids used in this example are defined as follows:

```
USER1                 USER2
NAME     TEST  USER1  NAME     TESTUSER2
DFLTGRP  SYS1         DFLTGRP  SYS1
CONNECT  SYS1         CONNECT  SYS1,GRP1,GRP2
```

During the RACLISTing process, when all relevant profiles are merged into an in-storage table, the two grouping resource profiles are combined:

```
TCICSTRN CEMT  UACC  NONE
ACL      USER1        READ
         GRP1         READ
```

After RACLISTing the profiles, the information about which profiles were used to build the in-storage profiles is no longer available.

When USER1 accesses the CEMT transaction, access is permitted based on both the RESGRP1 and the RESGRP2 profiles.

When USER2 accesses the CEMT transaction access is permitted based on the RESGRP2 profile because USER2 is a member of GROUP GRP1, which has access.

As this example illustrates, it is not always immediately obvious which profile is used to allow or prevent access.

zSecure Admin provides a reporting function that matches the access request to the best fitting *in-storage* merged profile. For that profile, zSecure Admin shows those profiles that were used to build it.

For the CEMT transaction, the access of USER1 is based on information in profiles RESGRP1 and RESGRP2. For USER2, access is based on RESGRP2. The UACC is based on information in profile RESGRP1. Depending on which userid attempts to access a particular transaction, the access authority is based on different profiles. For non-grouping resource classes, like data sets, access for all users is always based on a single best-fitting profile. For RACLISTed grouping resource classes, the profile used is dependent on the userid.

The Member usage reports show the different access usage in an easy to understand multi-level format.

To begin reporting member usage, select option **AM.6** from the zSecure Admin main menu to open the report selection panel shown in the Figure 500 on page 668.

```
 Menu         Options       Info    Commands     Setup

```

Figure 500. Member Usage report selection panel

For information about setting up the report, see "Setting up and generating the reports" on page 660.

Example: Reporting on Global Access Checking

The data collected by the RACF Access monitor includes information indicating whether a particular access request was satisfied using the Global Access Checking (GAC) table. The GAC Table is used to improve performance for public resources. It has entries that permit all users to have access to a resource. Each entry also specifies the access level permitted. (See "*Setting Up the Global Access Checking Table*", *RACF Security Server Administrator's Guide* (SA22-7683).)

In zSecure Admin, two options are available to report on access permitted using the GAC: Access Summary report (**AM.1**) and the Global Access Checking Usage report (**AM.7**).

The Access Summary report provides an overview of all access requests to all resources that were permitted using the GAC Table. To include this information in the report, you must specify the advanced selection criteria option for global access checking on the Further selection panel. For details, see "Reporting on actual profile usage" on page 649.

The Global Access Checking Usage report provides an overview of access permitted using the GAC based on the currently defined entries in the GAC Table.

To begin reporting member usage, select option **AM.6** from the zSecure Admin main menu to open the report selection panel shown in the Figure 501 on page 669.

```
 Menu         Options       Info    Commands     Setup
──────────────────────────────────────────────────────────────────────────────
                          zSecure Admin+Audit for RACF - Access - Global usage
Command ===> ____________________________________________________________

Show GLOBAL profiles that fit all of the following criteria:
RACF profile name . . . ____________________________________
Permit id . . . . . . . ________  (permit id or EGN mask on access list)
Complex . . . . . . . . ________  (complex or EGN mask)
Show accesses . . . . . _ Non-zero counts     _ Zero counts

Profile to use  _ 1. Use historic profile name in access summary if present
                  2. Simulate access in database to find current profile

Advanced selection criteria

Output/run options
_ Print format          Customize title     Send as email
    Background run
```

Figure 501. Member Usage report selection panel

You can set up the report to be generated based either on the actual historic use that has been made of the GAC Table or on a simulation using the current GAC Table. The history report uses the Access Monitor data and only reports on those access requests that were granted using the GAC table at the time of the access request. The simulate report analyzes all access requests and determines whether the current GAC table allows access. If the GAC Table has not been modified since the Access Monitor data was collected, the data in both reports is the same.

For information about setting up the report, see "Setting up and generating the reports" on page 660.

Reviewing the results

Figure 502 on page 670 shows Global Access Usage report results.

Use the Global Access Usage report to view the following types of information:

- A summary of access information for selected profiles categorized by result, (*allowed*, *denied*, and *unexplained* for example.
- Select an individual profile entry to view a summary of the access monitor information for that profile as shown in Figure 502 on page 670.
- In the profile view, select an individual access monitor record to view details about specific access events.

Figure 502 on page 670 shows a summary of the Global access table usage report for a specific profile.

```
Global access table usage

__     173           0 15Jun09 SYS1     READ    ISP.**
__       4           0 10Jun09 SYS1     UPDATE  SYS1.BRODCAST
__     209           0 15Jun09 SYS1     READ    USER.**
*********************** Bottom of Data ***********************
```

Figure 502. Global access table usage report

In the example shown in Figure 502, you can find the following information:

- 945 access requests to the DATASET class were satisfied using the GAC Table. You can see similar information for other resource classes.
- The entry for &RACUID.** is empty because the Access Monitor was running with the default option NOINCLUDEOWNRESOURCE. If this option is enabled, all access attempts to data sets where the High-level qualifier matches the userid requesting access are suppressed from the Access Monitor data sets. These types of access requests typically show access requests to data sets specifically created for a given userid without providing any interesting information. Suppressing these records is done by default.

To view more detailed information about an access event, type **S** in the entry field for any entry.

Generating RACF usage reports using only RACF data

To run a report based on information from the current RACF database, you can use Access Monitor RACF reporting option AM.6 without specifying an Access Monitor data set. When the AM.6 report is run without an Access Monitor data set, the results include information based on the definitions in the RACF database only. Information about usage access, available in the Acccess Monitor collection reports, is not included. The following fields are not included in the report: **Allowed**, **Deny**, **Unexp** and **LastUse**.

Use the SETUP FILES function on the zSecure Admin main menu to remove the Access Monitor data sets from the selected set of input data sources. How you remove Access Monitor data sets depends on how they are setup. If you created a separate input file set for the Access Monitor data sets, clear the selection. If you added Access Monitor data sets to an existing data set, you can delete all lines that specify ACCESS in the **Type** column.

Performing RACF database cleanup tasks

Although removing unused or obsolete definitions might seem straightforward, the process is more complex in practice because resource profiles and access definitions can be unused or obsolete for many different reasons. For example, resource profiles and access lists might appear to be unused or empty, but on further investigation you might discover that they are used only under certain conditions. Because of this complexity, decisions about whether to delete profiles or modify access lists often require further analysis.

zSecure Admin provides several functions that can help identify and remove obsolete or superfluous definitions. However, most of these functions are based on a static analysis of the data in the RACF database. Sometimes the static analysis indicates that a profile, access list entry, or group membership is redundant. However, in reality the definition might have been used in the recent past, or it might be needed in the future.

zSecure Admin also provides functions that can help identify unused resource profiles and authorizations based on actual usage. These functions are based on dynamic analysis of the data in Access Monitor data sets. However, a purely dynamic analysis of the data might ignore the fact that some apparently unused definitions do serve a purpose. For example, if a profile prevents a user from accessing a resource, and the user never tried to access the resource, the profile shows up as unused. The user never created an access violation, but that does not mean that the corresponding access list entry is useless. It is only unused. The profile and the access list entry are still required to prevent future access attempts.

zSecure Admin provides several functions that correlate the data from the static analysis with the data from the dynamic analysis. Using this information, RACF administrators can confirm or deny the conclusions reached based on analysis of either type of data alone.

Most RACF cleanup activities require a combination of static RACF profile analysis and dynamic analysis of actual RACF profile use.

The following scenarios describe different types of RACF database cleanup tasks using examples of resource profiles and Access list definitions.

Scenario 1: Removing profiles that do not cover any resources or that duplicate other profiles

The following examples describe these types of profiles.

- A `DATASET` profile such as `<hlq>.data.**` has no data set matching that name. Such a profile might be leftover from a time when the data set existed. In that case, the profile can be deleted safely. The profile might also be one that is explicitly defined to describe a data set that is created occasionally and later deleted. In this scenario, further analysis is required before deciding to delete or retain the profile.
- A `DATASET` profile covers `<hlq>.test.**` and another `DATASET` profile covers `<hlq>.**`. With these two profiles, the first is a more specific profile that is only used for some data sets. The profile might have been created at some time and forgotten afterward. At the moment, this profile is not necessary because the `<hlq>.*` profile covers the same resources. Having both profiles can confuse system administrators or support personnel. Also, if an Administrator or Support person wanted to grant a group or user access to all `<hlq>` profiles, they would have to update two profiles instead of one.

Scenario 2: Removing profiles whose security contribution is unclear
The following example describes a profile that is a candidate for this type of RACF database cleanup.

A DATASET profile such as <hlq>.test.** exists at the same time as an almost identical profile, <hlq>.**. The only difference is that the first profile has one additional group or user on the access list. For this example, assume that the additional entry is C2XUSER. The access level permitted for C2XUSER might be higher or lower than it would have been if the entry were not in the access list. Because the more specific <hlq>.test.** profile might result in higher or lower access for C2XUSER using the more specific profile, further research is required to determine whether it is safe to delete the profile.

Scenario 3: Removing users or groups from the Access List for a resource profile
The following examples describes items that are targets for this type of RACF database cleanup.

- A user is a member of a group. Both the user and the group are on an access list with the same access level. In this situation, the user can be removed from the access list because the user access level granted is the same for the user entry and the group entry.
- A group is in the access list of a resource with the same access level as the level of either ID(*) or the UACC. The access list entry for the group can be removed because the group access level is the same whether permitted by the ID(*), the UACC, or the group.
- A user is in the access list of a resource with the same access level as the level of either ID(*) or the UACC. None of the groups for the userid are in the access list, and the user also does not have any group or system level OPERATIONS attribute. In this case, the access list entry for the user can be removed because the user access granted is the same for the user, ID(*) or the UACC.

Scenario 4: Evaluating group membership
The following example describes items that are targets for this type of RACF database cleanup.

Users can be a member of multiple groups. Through group membership, users can be permitted access to resources. Some of these groups might not be present in any access list when the user has only USE authority. Although such groups might be ineffective at the moment, they might have been used in the past or might be used in the future. Further analysis is required to determine whether the group can be safely removed.

Removing profiles

There are several categories of profiles that are candidates for deletion.

Redundant profiles
Redundant profiles are identical to the next higher level generic profile. zSecure Admin users can use the REPORT REDUNDANT and REPORT NONREDUNDANT functions to report on and automatically remove redundant profiles. These functions are available from the Cleanup option on the Access Monitor menu **(AM.9)**. You can also generate reports and remove redundant profiles through a batch job. For more information about the REPORT (NON)REDUNDANT function, see "RA.3.3 Redundant - Finding and removing redundant profiles" on page 205.

Empty profiles
Empty profiles do not protect any resources. zSecure Admin users can use the VERIFY NOTEMPTY function to report on empty profiles. This function is

available from the Cleanup option on the Access Monitor menu (**AM.9)**. You can also generate reports through a batch job. For more information about the VERIFY NOTEMPTY function, see "Removing unused generic profiles" on page 362. One problem presented by an empty profile is determining whether the data set profile is permanently empty. For example, the profile might apply to a data set that is created temporarily and then deleted. Before removing empty profiles, save the list and evaluate the list against profiles included in the *Unused profiles* report.

Unused profiles

Unused profiles are the most difficult type of profile to cleanup. These profiles often do protect resources, and their definition differs from the definition of the next higher generic profile. However, if the profiles are not used it might be worthwhile to investigate why the profiles exist and determine whether they can be removed.

Unused profiles are often higher level generic profiles that are hidden by more specific generic (or discrete) profiles. For example, given the following profile definitions, the top generic profile (SYS1.**) might be an empty, unused profile.

```
SYS1.**   UACC(NONE)   SYSPROG(ALTER)
SYS1.LINK*  UACC(NONE)   SYSPROG(ALTER)
SYS1.LPA*  UACC(NONE)   SYSPROG(ALTER)
...
```

All existing SYS1 data sets in the system are protected by one of the lower-level profiles, such as SYS1.LINK*. The lower-level profiles are used, but the top generic profile is unused. Such profiles are sometimes called backstop or catch-all profiles because they are only in place to cover resources not defined more specifically by other profiles. The REPORT REDUNDANT (**AM.9.2**) and VERIFY NOT EMPTY (**AM.9.3**) functions take this situation into account. These options leave the top generic profile in place and focus on the more specific profiles. They are available from the Cleanup option on the Access Monitor menu (**AM.9**).

Based on the discussion of redundant, empty, and unused profiles, you can see that only redundant profiles can be removed automatically. Decisions about removing all other profiles such as empty and unused ones require analysis and human judgment before the profile can be deleted. There are several approaches to deleting profiles which are described in the following sections.

Creating a strategy for profile removal

Before removing profiles, develop a strategy to identify which class of profiles to remove and how to remove them. The available options are different for data set profiles and for general resource profiles. For data sets, when you define a data set profile, you create profile can be used to allow the creation (allocation) of a data set on disk. For general resource profiles, the creation of the resource is typically not related to the existence of a matching profile. Also, for data sets, users can be authorized to create profiles based on their connection to a certain group. zSecure Admin provides some special functions to help remove data set profiles. These special functions are REMOVE REDUNDANT and VERIFY NOT EMPTY. You can use both these functions from the Cleanup option on the Access Monitor menu (**AM.9**).

When you remove profiles, you have two options:

1. Use a process that relies on the Administrator to analyze and remove profiles manually.

With this option, the Administrator first generates and analyzes profile usage reports (**AM.5**), and then generates a command to remove obsolete profiles. This process is the best and safest method for profile removal.

2. Run an automated process without analyzing profile usage.

   With this option, you rely on the zSecure Admin analysis to identify unused profiles and mark them for deletion. However, as described in "Removing profiles" on page 672, running the automated process without analyzing the profile usage might not always result in removal of the least useful profiles.

Removing data set profiles

You can remove profiles using a combination of automatic and manual actions that require administrator analysis and action. The following process The process requires the following steps which are described in this topic.

1. "Remove redundant profiles."
2. "Analyze profile usage."
3. "Check for empty profiles" on page 676.
4. "Identify almost redundant profiles" on page 676.
5. "Remove obsolete profiles" on page 676.

Note: When you use the Access Monitor reporting functions, verify that the Access Monitor data sets you designate as data sources cover a time period that is long enough for you to decide with confidence that the profiles are never used.

Step 1: Remove redundant profiles

1. On the zSecure Admin command line, type **AM.9**. Then, press **Enter** to open the Access Monitor Cleanup menu.
2. Select **2 Dataset** to open the Reports Redundant panel to specify the selection criteria to target the redundant profiles that you want to delete. (For field help, press F1.)
3. Enter a / in **Remove redundant profiles** to generate the delete commands for the redundant profiles.
4. On the command panel, follow the instructions at the top of the panel to run the commands.

Step 2: Analyze profile usage

After removing the redundant profiles, the next step is to analyze unused profiles to determine which profiles can be removed safely.

1. On the command line, type **AM.9.5** and press enter to open the Profile usage panel.
2. To report on unused profiles, enter a / in **Zero counts** as shown in Figure 503 on page 675.

```
 Menu         Options       Info    Commands     Setup
 ──────────────────────────────────────────────────────────────────────────────
               zSecure Admin+Audit for RACF - Access - Profile usage
Command ===> ____________________________________________________________

     Background run
```

Figure 503. Profile Usage report - Selection Criteria for reporting on unused data set profiles

3. Specify any other report selection criteria required. (See "Reporting on RACF Usage" on page 658 for more information about generating reports.)
4. After entering the report selection criteria, press **Enter** to generate the report.

Figure 504 shows an example of the resulting Profile Usage report.

```

```

Figure 504. Profile Usage report showing unused data set profiles

This report shows all the data set profiles that have not been used for the time period for which access monitor records are available. If the report shows too many profiles, you can apply additional selection criteria to limit the results. For example, you can specify a data set name pattern. Selecting records based on user-specified criteria allows you to focus on selected profiles during the analysis. You can also use the **Advanced Selection** criteria. For example, you might specify profile creation date criteria to limit the report to the oldest profiles.

Use the **S** line command to review details of a particular profile in the report. For example, selecting the ASU.** profile in Figure 504 on page 675 opens the detail view shown in Figure 505.

```
Profiles, by class complex                                      Line 1 of 1

    Profile usage statistics
    Allowed                       0
    Deny                          0
    Unexp                         0
    Last use in access summary
```

Figure 505. Profile Usage report showing unused data set profiles

From this example, you can see that a total of three permits (including the UACC) have been permitted for this profile. The Profile usage statistics in this example also show that the profile has not been used during the measurement period.

Step 3: Check for empty profiles

After reviewing the profile usage information, the next step is to determine whether the unused profiles are empty.

1. On the command line, type **AM.9.3** and press **Enter** to open the Access Monitor Cleanup menu.
2. To identify profiles that are good candidates for removal, look for those profiles that are also included in the Profile Usage report for unused profiles

Step 4: Identify almost redundant profiles

After checking for empty profiles, the next step is to determine whether a profile is an almost redundant profile and analyze the reasons that it is not redundant. For more information about non-redundancy, see "RA.3.3 Redundant - Finding and removing redundant profiles" on page 205.

Step 5: Remove the obsolete profiles

For each profile identified in the analysis process, issue a RACF DELDSD command to delete the profile.

This same removal process can also be followed by running the Report redundant report (**AM.9.2**) or Verify Not Empty report (**AM.9.3**) first. After running these reports, generate the Profile Usage report for unused profiles and compare the results to the Redundant and Verify Not Empty reports to identify profiles that need to be removed.

Removing general resource profiles

The process for removing unused general resource profiles is different than the process for removing data set profiles. For example, zSecure Admin does not provide any function to verify that CICS, IMS, or DB2 resource profiles actually

match any resources for those subsystems. Consequently, you have to use another process to evaluate the usefulness of these general resource profiles. zSecure Admin does report about usage of these profiles, but the final decision about removing profiles must be made using additional criteria. Figure 506 shows a Profile Usage report with a list of unused general resource profiles by class.

```

****************************** Bottom of Data ********************************
```

Figure 507. Profile Usage report - Profiles by class detail view

After identifying potential unused profiles in the Profile Usage report, you can analyze the profiles to determine which ones need to be removed. If the results of the analysis indicate that a profile needs to be deleted, the administrator can issue the necessary RACF RDELETE commands to delete the profile.

Automatically removing unused profiles

You can automatically generate the applicable remove commands to remove unused profiles in a single step using the Access Monitor Remove Profiles option (**AM.8.1**). Using the automated process offers two significant benefits: the remove commands can be automatically generated based on user-specified selection criteria, and a recovery command file is automatically generated that can be used to restore profiles that have been removed in error.

When you run the recovery command file, profiles are restored to their original state. Some characteristics such as the creation date are different, but otherwise the recovered profiles are identical. For data set and general resource profile cleanup, the number of recovery commands generated is typically significantly larger than

the number of delete commands. This increase occurs because additional alter and permit commands are often required in addition to the define command for the profile.

Notes:

1. When using the automatic profile removal process, you must specify a matching CKFREEZE file in the data sources you specified using SETUP FILES. (See "SE.1 Setup - Input files" on page 1645). Without a matching CKFREEZE file, either the recovery file might be incomplete, or the ACL removal file might contain incorrect commands.
2. Automatic profile removal only works when exactly one RACF data source is selected in SETUP FILES. If more then one RACF data source is selected, an error message is issued.

Generating remove (delete) and recovery commands:

1. From the AM monitor menu, type AM.8 to open the Remove panel shown in Figure 508.

```
                  zSecure Suite - Access - Remove
Option ===> ____________________________________________

1    Profiles        Remove unused profiles
2    Permits         Remove unused permits
3    Connects        Remove unused connects

Recovery command file
BCCG011.RECOVERY.CKRCMD_____________
```

Figure 508. Access Remove unused profiles, permits, and connects panel

2. In the **Recovery command file** field, type the name of a permanent data set to save the recovery commands.

   The recovery command file is overwritten each time a Remove operation is performed. If you want to save recovery command files from previous remove operations, specify a new data set name for each recovery operation.
3. Select the Remove option required.
4. On the Remove selection criteria panel, specify the selection criteria for items you want to remove. Use the Advanced Selection criteria options if necessary.
5. Press **Enter** to generate the commands.

Removing access and connects

Other types of information that you might want to remove are access list entries and group connections that are not being used. zSecure Admin provides an independent cleanup function to remove all userid-based access list entries that are unnecessary. Running this Remove Redundant Permits function first results in a more complete cleanup of the access list entries.

During the access verification process, RACF checks whether the userid that is requesting access is included on the access list. If the userid is present, RACF grants or denies access based on that access list entry. In this situation, group-membership is not considered. This same approach is used by zSecure Admin to determine which ACL entries are used. This processing logic means that if a user has the same access that is granted through one of its groups, the group access is not considered, and all access is counted towards the userid ACL entry. As a result, the ACL entry for the userid is classified as used and the ACL entry

for the group is classified as unused. Because access control through groups is the preferred method, counting on these redundant userid-ACL entries is undesirable. To remove these confusing and unnecessary ACL entries and enable proper counting of the use of group-related ACL entries, run the Remove Redundant Permits function at the beginning of the cleanup process

After you remove redundant permits, you can analyze and remove unused permits and connects. For details, see the following sections.

- "Removing redundant permits"
- "Manually remove unused permits"
- "Automatically removing unused permits" on page 681
- "Manually remove unused connects" on page 681
- "Automatically removing unused connects" on page 683

Removing redundant permits

Redundant permits are those permits that provide the same level of access that a user already has through membership in a group. In this case, removing the user from the access list results in RACF using the highest access permitted by the user's connect groups. If the access is the same, the access permitted using the specific user ID ACL entry is considered a *redundant permit*. Removing redundant permits can typically be done without any adverse effect.

1. On the command line, type **AM.9.2** and press **Enter** to generate the commands to remove the redundant permits.
2. On the command panel, follow the instructions at the top of the panel to run the commands.

For additional information about removing redundant permits see the REDUNDANT_PERMIT keyword in "REMOVE" on page 870.

Manually remove unused permits

The following process demonstrates how to remove unused access list (ACL) entries manually based on administrative analysis. Verify that the Access Monitor data sets you designate as data sources cover a time period that is long enough for you to declare an entry as obsolete. (See "Setting up zSecure to analyze and report on Access Monitor data" on page 647.)

Step 1. Review unused ACL entries.

Step 2. Verify that ACL entries are not being used.

Step 3. Delete the unused ACL entries.

Step 1: Reviewing unused ACL entries

1. On the command line, type **AM.3** and press **Enter** to open the Permit usage panel.
2. To report on unused connects, enter a / in the **Zero counts** field.
3. Specify any other report selection criteria required. (See "Reporting on RACF Usage" on page 658 for details about specifying selection criteria.)

   If you want to remove almost unused ACL entries, or want to remove ACL entries that have not been used for a long time (stale entries), select the applicable **Advanced selection criteria**.
4. After entering the report selection criteria, press **Enter** to generate the report.

Step 2: Verifying that ACL entries are not being used

On the Permit Usage report, you can review the unused ACL entries by using the **S** line command for the class you are interested in. Figure 509 shows the ACL entries for the FACILITY class.

```
Unconditional permits and UACC, by class complex/profile
Command ===>  ____________________________________________________
Permit and UACC usage, zero counts
   Allowed Deny  Unexp LastUse Class    Complex
__       0     0     0         FACILITY SYS1
   Allowed Deny  Unexp LastUse Type     Profile
__       0     0     0         DISCRETE STGADMIN.EDG.LIST
   Allowed Deny  Unexp LastUse Id       Access    Used    Failed  Red RdM
__       0     0     0         -UACC-   NONE                      No
__       0     0     0         DFHSM    READ                      Yes
__       0     0     0         IBMUSER  ALTER                     No
__       0     0     0         SYSPROG  UPDATE                    No
__       0     0     0         SYS1     ALTER                     No
****************************** Bottom of Data ******************************
```

Figure 509. Permit Usage report - Unused permits for a selected class

Evaluate the individual ACL entries using your knowledge of the environment and the information provided by the **Red** and **RdM** columns.

Red field

The **Red** column indicates whether the ACL listed in the panel reduces the access level for the specified user or group ID. If the value is *Yes*, the ACL grants a lower access level than the access that would be granted if the ACL entry was removed. For example, in Figure 509 the `DFHSM` userid has READ access to the FACILITY class profile shown (*SYS1*). If this ACL entry is removed, the userid `DFHSM`, which is probably used to run the started task for DFSMShsm, has a higher access.

Entries that have *Yes* in the **Red** field require further investigation to determine whether an ACL entry can be safely removed. To investigate, you can run a RACF `Listuser DFHSM` command to determine group membership for the userid and access level granted by each group identified. In this example, the investigation determines that the userid `DFHSM` is a member of the group `SYSPROG`. Figure 509 shows that the SYSPROG group has UPDATE access. So if the ACL entry is removed, the effective access level for the userid `DFHSM` changes to UPDATE which might allow a higher access level than intended.

RdM field

Like the **Red** field, the **RdM** column indicates that the ACL entry represented reduces the access level for the specified ID. The **RdM** field value is *Yes* if the access shown is less than the access granted through an ACL entry in another profile which is merged with the current profile during the RACLIST process.

Entries that have *Yes* in the **RdM** field require further investigation to determine whether the ACL entry can be safely removed.

You can also use the **S** line command to view the details for a particular ACL entry. On the resulting display, use the **L** line command to run the appropriate RACF LIST command for the userid or group.

Step 3: Removing unused ACL entries

After verifying that an ACL entry is not being used, you can use the **D** line command to delete it.

1. In the line command area for the entries you want to delete, type **D**.
2. Press **Enter** to generate the commands.

3. On the Confirm panel, verify and edit the commands as required, and set the mode to run the commands.

   If you want to be able to restore deleted ACL entries, use the automatic deletion method for the ACL entries you identified for deletion during your analysis.

Automatically removing unused permits

You can automatically generate the applicable delete commands to remove unused permits in a single step using the Access Monitor Remove Permits option (**AM.8.2**). The automated process offers several significant benefits:

- Automatic generation of the delete commands based on user-specified selection criteria including the creation date of the profile and the usage dates of the ACL entry.
- Automatic generation of a recovery command file to re-establish the access list entries that are deleted.
- You do not need to visually inspect every `Red` and `RdM` flag setting.
- Commands are generated to reset the UACC to NONE.
- You can generate multiple delete commands in a single operation.

In the absence of any selection criteria, all unused ACL entries are selected for deletion. The universal access (UACC) is handled like regular ACL entries. The UACC is represented by the pseudo ID `-UACC-`, and the generated commands are ALTDSD and RALTER.

Note: When using the automatic deletion process, you must also specify a matching CKFREEZE file in the data sources you selected using SETUP FILES. (See "SE.1 Setup - Input files" on page 1645.) Without a matching CKFREEZE file, either the recovery file might be incomplete, or the ACL removal file might contain incorrect commands.

Manually remove unused connects

The following process demonstrates how to remove unused connects manually based on administrator analysis and action. Make sure that you have collected sufficient usage information to declare an entry as unused. Before removing any access, verify that the Access Monitor data sets you designated as data sources cover the time period that you intended. (See "Setting up zSecure to analyze and report on Access Monitor data" on page 647.)

Step 1. Review unused connects.

Step 2. Verify that group connections are not being used.

Step 3. Delete the unused connects.

Step 1: Reviewing unused connects

1. On the command line, type **AM.4** and press **Enter** to open the Connect usage panel.
2. To report on unused connects, enter a / in the **Zero counts** field.
3. Specify any other report selection criteria required. (See "Reporting on RACF Usage" on page 658 for details on specifying selection criteria.)

   If you want to remove *almost unused* connects or connects that have not been used for a long time (stale connects), select the Advanced Criteria options to specify the applicable selection criteria to report on these types of connects.
4. After entering the report selection criteria, press **Enter** to generate the report. Figure 510 on page 682 shows a Connect Usage report with a list of

unused connects.

```
Connect authority use, by group
Command ===> _____________________________________________
Connect usage, zero counts
Allowed Deny  Unexp LastUse Group    Complex  InstData
__   0     0     0          #EMPLOY  SYS1
__   0     0     0          #READ    SYS1
__   0     0     0          ADB210   SYS1
__   0     0     0          ADCD     SYS1
__   0     0     0          AOP      SYS1
__   0     0     0          APS330   SYS1
__   0     0     0          ASU      SYS1
__   0     0     0          AUT220   SYS1
__   0     0     0          AUT230   SYS1
__   0     0     0          CMDTEST  SYS1
__   0     0     0          CRMA     SYS1
__   0     0     0          CRMB     SYS1
__   0     0     0          C2RSERVG SYS1
__   0     0     0          C2XGRP   SYS1
```

Figure 510. Connect Usage report - Unused connects

Step 2: Verify that group connections are not being used

The Access Monitor program only records regular access verification requests. Consequently, the use of group connections for other purposes is not recorded. For example, a group connection can also be used to define new data sets and new data set profiles to connect users to the group and even to define new groups. Most of these actions are not recorded by the Access Monitor program.

Before deleting unused connections from the unused connect list, you must verify that the group connections in the list are not being used. The authorizations required for group connections being used for unrecorded actions typically involve either a group connect-authorization higher than USE, or a non-default connect-attribute, like group-special or group-operations. You can review the connect authorization for group connects and the connect attributes for users from the Connect Usage report.

1. On the Connect Usage report, type **S** in the line command area for a group connect entry.
2. Press **Enter** to see the detailed information for the group connection as illustrated in Figure 511.

```
 Connect authority use, by group
Command ===> _____________________________________________
Connect usage, zero counts
    Allowed Deny  Unexp LastUse Group    Complex  InstData
__        0     0     0         SYS1     SYS1
    Allowed Deny  Unexp LastUse Userid   Access  Name                RI DfltGrp
__        0     0     0         BPXOINIT USE     BPXOINIT               SYS1
__        0     0     0         CICSDFLT USE     CICS DEFAULT         Y SYS1
__        0     0     0         CICSUSER USE                            SYS1
__        0     0     0         DB8GRFSH USE                            SYS1
__        0     0     0         DB9GENV5 USE                          Y SYS1
__        0     0     0         DB9GRFSH USE                          Y SYS1
__        0     0     0         DSN1WLM1 USE                            SYS1
__        0     0     0         FTPD     USE     FTPD                   SYS1
__        0     0     0         IBMUSER  JOIN    NAME                Y  SYS1
__        0     0     0         IMS71CR1 USE     IMS                  Y SYS1
__        0     0     0         IMS71DL1 USE     IMS                  Y SYS1
```

Figure 511. Connect Usage report - Connect authority use by group detail view

In this example, the SYS1 group includes the user IBMUSER with JOIN authorization. Because this authorization level is higher than USE, this group connection is not a good candidate for removal. The display also shows the default group (DFLTGRP) for the userid. The default group cannot be removed from a userid.

3. To determine whether a userid has a non-default group-attribute, use the **S** line command to view the detailed user information. Then, use the **L** command to LIST the userid profile. If the user to group connections show any non-default attribute, carefully evaluate how the connect is used before deciding to delete it.

Step 3: Remove the unused connects

After verifying that a connection is unused, use the **D** line command to delete it from the Connect Usage detail view shown in Figure 511 on page 682.

1. In the line command area for the entries you want to delete, type **D**.
2. Press **Enter** to generate the commands.
3. On the Confirm panel, verify and edit the commands as required and set the mode to run the commands.

   If you want to be able restore the connects after removal, you might want to use the automatic removal method.

Automatically removing unused connects

You can automatically generate the applicable remove commands to remove unused connects in a single step using the Access Monitor Remove Connects option (**AM.8.3**). Using the automated process offers several significant benefits:

- Automatic generation of the remove commands based on user-specified selection criteria.
- Automatic generation of a recovery command file to restore connects that have been removed if required.
- You do not have to visually inspect every connect to be removed.
- You can generate multiple remove commands in a single operation.

Note: zSecure Access Monitor does not collect access information for Unix directories and files inside zFS and HFS files systems. RACF connect groups that are only used for access to Unix files are therefore not detected as being used. Such RACF groups are included in the command files for connect removal. Before running the generated commands, verify that no connections required for access to Unix files are removed.

When you use the automatic connect removal process, USE level group-connections with default group-attributes that have not been used during the recorded period are deleted. The Advanced selection criteria allow selection on the connection of the user to the group and selection on the usage dates of the connect. In the absence of any selection criteria, all unused group connections are selected for deletion.

Note: When using the automatic connect removal process, you must also specify a matching CKFREEZE file in the data sources that you specified using SETUP FILES. (See “SE.1 Setup - Input files” on page 1645). Without a matching CKFREEZE file, either the recovery file might be incomplete, or the connect removal file might contain incorrect commands.

Consolidating data collected by Access Monitor

Table 277 describes the different types of Access Monitor consolidation data sets that can be used in Access Monitor reporting and database cleanup activities.

Table 277. Access Monitor program - consolidation data set types

Type of consolidation data set	Description
Daily consolidation data set	Access Monitor automatically collects access event data at a defined SMF interval (the default is 30 minutes) and writes the data to a data set. The SMF interval is defined by the INTVAL parameter in member SMFPRMxx in PARMLIB. At the end of the day, these data sets are consolidated into a single data set. This consolidation summarizes similar data within the collection data sets for each interval. The individual data sets created for each interval during the day are deleted. As part of the consolidation process, all records for similar events are combined and counted together. In the combined record, only the date and time of the last occurrence for each event is kept.
Consolidation data set for installation-defined interval (weekly, bi-weekly, or monthly)	An installation can define a manual or automated task to summarize similar data within the consolidated daily files. Then, the summarized data can be written to a file containing weekly, bi-weekly, or monthly data, for example. The main purpose for this secondary consolidation is to reduce the file size and processing time required to generate reports. However, this type of consolidation can result in a loss of detailed event information. For example, if consolidation is done in a monthly file, the resulting reports cannot be used to determine whether a user accessed a particular resource two weeks ago. The monthly consolidation process only retains information about the last file access for the month, not a week within the month.
User-created consolidation data sets.	Users can create their own Access Monitor data sets by submitting a batch job that consolidates existing data sets. For example, if the Access Monitor program has been configured to create daily and monthly consolidation data sets. A user who wanted a weekly consolidation data set can create one by consolidating the daily data sets for a given week.

The type of consolidation sets available in your installation depend on the configuration options selected during installation and deployment. The sample jobs provided with zSecure Admin use a monthly consolidation scheme.

During the monthly consolidation process, the existing daily files are deleted. Your installation might decide to run the monthly process in the second half of the month to retain detail information for a longer period. A second step in the sample job consolidates the last 12 months of data into a single file. The data set names in the sample jobs use the following naming conventions:

```
-hlq-.C2PACMON.Dyymmdd.Thhmm  30-minute interval
-hlq-.C2PACMON.Dyymmdd     Daily consolidation file
-hlq-.C2PACMON.Myymm     Monthly consolidation file
-hlq-.C2PACMON.Y12mon     Last-12-months consolidation file
```

If the sample consolidation process is implemented, the consolidation data sets for the installation will be like the ones shown in the following examples.

Daily consolidation files

```
03-Dec 2008   <hlq>.C2PACMON.D081203
02-Dec 2008   <hlq>.C2PACMON.D081202
01-Dec 2008   <hlq>.C2PACMON.D081201
```

Monthly and yearly consolidation files

```
                Monthly file      Yearly file
01-Nov 2008 - 30 Nov 2008   <hlq>.C2PACMON.M0811  <hlq>.C2PACMON.Y12MON
```

For instructions to set up the daily and monthly consolidation processes for your site, see the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

You can perform a manual consolidation using a job like the sample job C2PJCOND provided in the SCKRSAMP data set. The sample job assumes that the output data set exists. After successful processing, it deletes the data sets fed into the consolidation process. To run your own consolidation, you must create the output Access Monitor data set and specify the data sets to be fed into the consolidation process without the DELETE option as shown in the following code sample.

```
//CKRCARLA EXEC PGM=CKRCARLA,REGION=64M
//STEPLIB  DD DISP=SHR,DSN=&CPREFIX..SCKRLOAD
//C2PACMON DD DSN=your.output.accmon.dataset,
//            DISP=(MOD,CATLG),VOL=SER=&VOLSER.,
//            SPACE=(CYL,(1,1)),
//            RECFM=VB,LRECL=584,BLKSIZE=27998
//SYSPRINT DD SYSOUT=*
//SYSIN    DD DATA,DLM=##
ALLOC TYPE=ACCESS DSN=your.input.accmon.dataset
ALLOC TYPE=OUTPUT DD=C2PACMON
include dd=sckrcarl member=c2pamcon
##
//SCKRCARL DD DISP=SHR,DSN=&CPREFIX..SCKRCARL
```

Figure 512. Sample JCL for consolidating Access Monitor data

You can repeat the `ALLOC TYPE=ACCESS` statement for as many data sets as needed. Alternatively, you can use DSNPREF to specify the prefix of all data sets that need to be consolidated. This sample job uses standard CARLa script to perform access monitor data consolidation (`C2PAMCON`). If you want to apply the consolidation to a subset of the input records, you can code your own version of this CARLa script, using appropriate SELECT statements. (See Chapter 12, “CARLa Command Language,” on page 713.)

Data reduction of Access Monitor data

The daily, monthly and yearly consolidation process as described in “Daily collection and consolidation” on page 646 combines multiple records for similar events into a single record. During this process, information about the exact moment at which the events occurred is discarded. Only the timestamp of the last occurrence is kept in the single output record. The counters for the number of times that the event occurred are added together and also kept in the single record. This method of combining multiple records is called consolidation. Hardly any information is lost.

For some situations, the consolidation process is not efficient. For example, every day a data set is created and used and the data set name has a qualifier with

today's date. While logically all these data sets belong together, the Access Monitor records for those data sets are not consolidated across multiple days. Another example is the use of Generation Data Groups (GDGs). Every generation data set within the group has a unique name. In RACF, the generation number is often irrelevant, but because of the different last qualifier the Access Monitor records are not consolidated for the entire generation data group. zSecure Admin provides several functions to process and discard part of resource names and other fields in the Access Monitor records. Use of these functions is called data reduction. Some information about the original event is permanently lost.

Several common data reduction methods can be invoked using built-in support for specific data set resources. Unless overruled during installation and deployment of Access Monitor, these common data reduction methods are applied during the automatic daily consolidation process. The available common data reduction functions are as follows:

SUPPRESS ACCESS_GDG_VERSION
The last qualifier of generation data sets is mapped onto GnnnnVnn.

SUPPRESS ACCESS_JESSPOOL_JOBID
The JOBID qualifier of JESSPOOL profiles (4th qualifier) is mapped onto Sxxxxxxx, Jxxxxxxx or Txxxxxxx, depending on the first character of the qualifier.

SUPPRESS ACCESS_JESSPOOL_DSID
The DSID qualifier of JESSPOOL profiles (5th qualifier) is mapped onto Dxxxxxxx if the first character of the qualifier is the character D.

It is also possible to perform more advanced data reduction using the CONVERSION statement as described in section “CONVERSION” on page 737. An example of such data reduction is shown in the following CARLa example.

```
conv type=access date3 replchar((substr(qual3,2,8),'d')),
     where (class=dataset,
            qualnum(resource)=4,
            qualif(resource,2)='C2PACMON',
            substr(qualif(resource,3),1,1)='D')
conv type=access time4 replchar((substr(qual4,2,8),'t')),
     where (class=dataset,
            qualnum(resource)=4,
            qualif(resource,2)='C2PACMON',
            substr(qualif(resource,4),1,1)='T')
...
 summary ,
...
 resource(0 l1char conv(date3,time4)) | ,
...
```

Figure 513. Data reduction example using CARLa CONVERSION statement

In this example, the conversion rules date3 and time 4 are defined. The intention is to apply data reduction to data set names with the following pattern:

```
HLQ.C2PACMON.D110819.T1556
```

The rules are rather simple and assume that all resources of type DATASETS with 4 qualifiers, with the second qualifier equal to C2PACMON, and the third qualifier starting with a "D", or the fourth qualifier starting with a "T" should be combined. In the target field, the rest of that third or fourth qualifier is replaced by lowercase "d" and "t".

In the WHERE clause, the conversion rules test the contents of the CLASS field and the format of the RESOURCE field, but the conversion rules do not specify which field should be the target of the data reduction. They only specify the method of data reduction. The target field of the data reduction is decided by the use of the CONV specification in the fields that are included in the SUMMARY statement. In this example, this is also the RESOURCE field. When used on the RESOURCE field, the dsname shown before is reduced to:

```
HLQ.C2PACMON.Ddddddd.Ttttt
```

Because the dsname now has no date and time specific information, the records for this resource can be consolidated with those for other dates or times. The original dsname is not available in the consolidated records.

Data reduction as specified in member C2PAMMAP in the SCKRCARL library occurs automatically during the daily consolidation. If you want to perform manual data reduction you can make a copy of the C2PAMMAP and C2PAMCMP members and use them in a job similar to the one shown in Figure 513 on page 686. Change the data set name and the include statement to match your setup. The C2PAMCMP member also uses the POE and JOBNAME selections currently configured in the parameter library. The ddnames C2PAMJOB, C2PAMRCL, and C2PAMPCL should point to data sets that contain applicable data, as described in "Configuring Jobname and POE-data collection" on page 646.

Converting Access Monitor Data

Access Monitor records can be in two different formats. The first format is the one used in zSecure Access Monitor for V1.12 and earlier releases. This format was introduced in zSecure V1.11, and is called the V1.11 format. The other format is the one introduced in zSecure Access Monitor V1.13, this format is called the V1.13 format. The benefit of the V1.13 format is that it allows for a much faster consolidation by processing all input files in parallel. All sample CARLa members in SCKRCARL and SC2PSAMP create data using the V1.13 format.

For reporting and analysis purposes, you can use any combination of V1.11 format and V1.13 format data.

If you want to consolidate existing Access Monitor data in V1.11 format, you cannot use CARLa member C2PAMCON. Before consolidating, V1.11 format data must be converted to the V1.13 format. You can do the conversion using the same procedure as outlined in "Data reduction of Access Monitor data" on page 685. The data reduction process can use any combination of V1.11 format and V1.13 format data, and always creates data using the V1.13 format. It is also possible to do the conversion using a simpler CARLa that does not perform any data reduction. Member C2PAMCVT in SCKRSAMP is provided for this purpose. It does not specify any data reduction, but only performs a direct conversion to the V1.13 format. The output is written to DDNAME C2PACMON. Use this CARLa in a job similar to the one shown in Figure 513 on page 686. Change the Access Monitor data set names and specify member C2PAMCVT in the include statement.

The conversion process can require a significant amount of CPU time and virtual storage, similar to the consolidation process used in zSecure V1.12 and earlier releases. If the required virtual storage is more than what's available, you can split the conversion process into smaller parts. This requires adapting the CARLa as provided in C2PAMCVT. Make a copy of this member and insert applicable CARLa SELECT and EXCLUDE statements to define subsets of Access Monitor records. For example one subset could be all records for CLASS=DATASET,

another for CLASS=JESSPOOL, and a third for all other classes. Another method could be to define the subsets based on userid ranges or resource name ranges. Use separate jobs or job steps to run conversion process on the defined subsets of Access Monitor records. Next use the regular consolidation process (for example using C2PAMCON) to consolidate the converted subsets into a single data set containing all converted records.

Chapter 11. Calling zSecure

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•	•	•	•	•	•	

Note: If the RACF database is shared between z/VM and z/OS systems, perform all RACF administration and auditing functions using zSecure for the z/OS system. RACF on z/VM does not support some profiles, segments, and fields in the RACF database. As a result, you can create errors in the database if you change, copy, or recreate profiles from Tivoli zSecure Manager for RACF z/VM. You can use zSecure for z/OS to work with any profile in the shared database because z/OS supports all profiles, segments and fields in the RACF database, including fields like `VMMDISK` that are specific to z/VM.

If your database is shared, use the following procedure to capture the information from the z/VM system and analyze it using zSecure on the z/OS system.

1. Use Tivoli zSecure Manager for RACF z/VM to create and update a `CKFREEZE` file from the z/VM system.
2. Transfer the `CKFREEZE` file to the z/OS system for RACF administration and auditing.

You can call IBM Security zSecure for z/OS from the environments listed in Table 278. Other environments are not supported.

Table 278. Supported environments

Supported Environment	**For more information, see...**
ISPF in TSO	"Starting the interactive component" on page 9
Batch	"Starting zSecure programs using JCL" on page 690
TSO outside of ISPF and in Batch	"Starting zSecure through line mode commands" on page 696
z/OS UNIX System Services	"Starting zSecure through line mode commands" on page 696
CICS is only supported by zSecure CICS Toolkit	*IBM Security zSecure CICS Toolkit: User Guide*
IBM Tivoli zSecure Manager for RACF z/VM is only supported on z/VM systems	*IBM Tivoli zSecure Manager for RACF z/VM: User Reference Manual*

For more information, see the following topics:

"Starting zSecure programs using JCL" on page 690
"Starting zSecure through line mode commands" on page 696
"IBM Security zSecure JCL procedures" on page 696
"IBM Security zSecure jobs" on page 699
"Using the scripts in the IBM Security zSecure CARLa library" on page 706

Starting zSecure programs using JCL

Table 279 provides an overview of IBM Security zSecure programs that can be called using batch jobs. Each program provides a link for additional information about JCL that can be used to call the program.

Table 279. Calling IBM Security zSecure programs using batch jobs

Program	Description	Details on calling through JCL
CKRCARLA CKRCARLX (used when APF authorization is required)	Uses the special purpose Auditing and Reporting language (CARLa) to process RACF SMF, Access Monitor, and other types of information. The program is used by the following zSecure products: Admin, Audit, Alert, Visual, and the Compliance Insight Enabler for z/OS.	"CKRCARLA and CKRCARLX" on page 691
CKGRACF	Used for handling Queued commands (like temporary access), revoke or resume schedules, User data fields and various other functions that require updating RACF profiles. This program is used by zSecure Admin and zSecure Visual.	"CKGRACF" on page 693
CKNSERVE	The main program for the zSecure Server that performs the necessary functions for communicating with remote systems to route commands and access RACF databases, SMF input files, CKFREEZE data sets, and other defined data sets.	For more information on the zSecure Server, see the "Using remote data" on page 4 and the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.
CKX (Command Execution Utility)	CKX is the IBM Security zSecure Command Execution Utility that issues TSO commands. Contrary to directly executing the commands with IKJEFT01	"CKX - Command Execution Utility" on page 693
C2PACMON (Access Monitor)zSecure Admin	Collects information about RACF usage data that can be used to remove unused or obsolete resource profiles or test usage scenarios. This program is supported by zSecure Admin.	*IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*

Table 279. Calling IBM Security zSecure programs using batch jobs (continued)

Program	Description	Details on calling through JCL
C2XACTV (RACF Exit Activator)	Provides dynamic exit support for some RACF exits. This script installs the exits required by various zSecure products including zSecure Admin, Audit, Alert, and IBM Tivoli Compliance Insight Manager Enabler for z/OS.	"C2XACTV - RACF Exit Activator" on page 693
CKFCOLL (zSecure Collect)	The zSecure Collect program, CKFCOLL gathers information about your z/OS system configuration. The program is designed to collect data quickly using minimal system resources. The data collected is analyzed by the CKRCARLA program.	"Configuring zSecure Collect" on page 1594
RACF Offline	Function for running and testing RACF commands on a RACF database that is not active in the system. This function is available in zSecure Admin.	"Activating" on page 596

CKRCARLA and CKRCARLX

CKRCARLA, the main program of zSecure Admin and Audit, performs the following functions:

- Interprets the CARLa code.
- Collects data from the security database, CKRFREEZE files, SMF, and other data.
- Generates reports based on the data collected.

Typically, CKRCARLA runs without APF authorization. If APF authorization is required, you can use the front-end program CKRCARLX. Using CKRCARLA with APF requires READ access to resource CKR.CKRCARLA.APF. For details, see *Appendix B: zSecure-specific security resources* in the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

Chapter 12, "CARLa Command Language," on page 713 describes which functions require APF authorization. Running with APF authorization affects any Writer to Operator (WTO) messages that might be issued: For programs without APF authorization, the system prefixes all WTO messages with a +. As a result, your message automation might be impacted when operation switches between programs running with APF authorization and programs running without it. To prevent message spoofing, CKRCARLA prefixes a + to any message that does not start with C2P1 through C2P8 when running with APF authorization. The changes can also disturb alignment in a multiline WTO message.

To call the IBM Security zSecure main program in batch mode, use the IBM Security zSecure cataloged procedure C2RC, for example:

```
// JCLLIB ORDER=(MY.CKRPARM,CKR.SCKRPROC)
//  EXEC  C2RC,ALLOCCKF=1,CONFIG=MYCONFIG
//SYSIN   DD *
  n type=system
  sortlist  sysname esmname esmlevel
```

If the zSecure procedures and configuration file are configured for your system and available in a standard procedure library, you can leave out the JCLLIB statement. Check with your system administrator for information.

For information about the zSecure cataloged procedures, see "IBM Security zSecure JCL procedures" on page 696.

For more control over file allocation, you can start CKRCARLA using the following code:

```
 //   INCLUDE  MEMBER=MYCONFIG
 //ZSECURE EXEC PGM=CKRCARLA,REGION=128M,
//    PARM='ALLOCATE INDD=CARLA OUTDD=REPORT'
//STEPLIB  DD DISP=SHR,DSN=&CPREFIX..SCKRLOAD
//REPORT   DD SYSOUT=*
//CARLA    DD *
 <subsequent CARLa>
```

In this example, the PARM field contains the first CARLa command. You can specify multiple commands separated by a semicolon.

This ALLOCATE statement reads the commands from the ddname CARLA instead of using the default SYSIN. Reports and messages are redirected to the ddname REPORT instead of using the default SYSPRINT. Because of this redirection, the CKRCARLA program does not need any fixed ddnames, except for STEPLIB. For information about the CARLa syntax, the ALLOCATE command, and how to redirect other DD statements, see Chapter 12, "CARLa Command Language," on page 713.

You can concatenate data sets with like attributes for all input ddnames. However, do not concatenate data sets that contain CKFREEZE or UNLOAD files. DD-statements used to specify these input files only require a single file, so concatenation is not necessary.

Two-pass queries

For two-pass CARLa queries the procedure C2RC2 is available. See "IBM Security zSecure JCL procedures" on page 696. C2RC2 is a nested JCL procedure, the procedure uses another procedure C2RC to do its work. There is a restriction in z/OS Job Control Language on overriding statements in nested procedures. Overriding is restricted by so many rules that in practice it is impossible. You can use the procedure C2RC two times to do the same.

A partial example of JCL for a two-pass query:

```
//* generate CARLa statements to be used in pass 2
//STEP1    EXEC C2RC,CONFIG=&CONFIG.
//CKR2PASS DD DISP=(NEW,PASS),UNIT=SYSDA,SPACE=(255,(2000,2000))
//    DSN=&&PASS1
//SYSIN DD *
  option dd=ckr2pass nopage
  newlist type=racf outlim=1
    sortlist  "report scope=(,"

  newlist type=racf
    s c=user s=base operations
    sortlist  key(8) ","

  newlist type=racf outlim=1
```

```
    sortlist  ")"
/*
//* Execute the CARLa generated by STEP1
//STEP2    EXEC C2RC,CONFIG=&CONFIG.
//SYSIN DD DISP=(OLD,PASS),DSN=&&PASS1
```

CKGRACF

A typical way to start CKGRACF is:

```
//   INCLUDE  MEMBER=MYCONFIG
//CKGRACF  EXEC PGM=CKGRACF,REGION=6M,PARM='INCLUDE DDNAME=CKGIN'
//STEPLIB  DD DISP=SHR,DSN=&CPREFIX..SCKRLOAD
//CKGPRINT DD SYSOUT=*
//SYSTERM  DD SYSOUT=*
//CKGIN    DD *
 <subsequent CKGRACF commands>
```

The INCLUDE statement in the PARM field is necessary to process an input ddname.

Without redirection, you can use the ddnames listed in "Supported file definitions for CKRCARLA" on page 701.

CKX - Command Execution Utility

CKX is the IBM Security zSecure Command Execution Utility that issues TSO commands. This utility differs from the IKJEFT01 utility for directly executing commands in the following ways:

- CKX returns a nonzero return code if any command had a nonzero returncode. not just the last one like IKJEFT01 only returns a nonzero return code if the last command has one.
- At the bottom of the CKXDEBUG file, CKX summarizes command failures for reviewing. IKJEFT01 does not provide a summary which makes it more difficult to note all the failed commands, especially when hundreds or thousands of commands are run.

You can start CKX using the following code:

```
//   INCLUDE  MEMBER=MYCONFIG
//CKX     EXEC PGM=IKJEFT01,REGION=64M,PARM='CKX DD=CKX@IN'
//STEPLIB  DD DISP=SHR,DSN=&CPREFIX..SCKRLOAD
//CKXDEBUG DD SYSOUT=*
//SYSTSPRT DD SYSOUT=*
//SYSTERM  DD SYSOUT=*
//SYSTSIN  DD DUMMY
//CKX@IN   DD *
 <CKX commands here>
```

Optionally, you can allocate the file CKXT@PRT. This file contains the data created by TSO commands called from the product. The default settings for following DCB parameters are: LRECL=255 and RECFM=VB. Line length is 251, except when sending data to a z/OS UNIX path. For UNIX system, the line length is 32752. Block size defaults to half track if a full track is larger than 32 KB.

C2XACTV - RACF Exit Activator

The RACF Exit Activator program, C2XACTV provides dynamic exit support for some RACF exits. The RACF Exit Activator program is designed primarily for installing the exits required by various zSecure products.

The RACF Exit Activator program offers support for RACF pre-, main-, and post-exits. If you already have RACF exit routines in place, the program uses these routines as sub exits. Before using the zSecure exits, confirm that the exit routines can coexist with the RACF exit routines.

In most cases, you do not need to control the exit explicitly:

- The C2XEXITS parameter controls the ICHPWX01 exit. This parameter is specified in the zSecure configuration files used by zSecure Alert and the Tivoli Compliance Insight Manager Enabler for z/OS.
- The other exits are automatically activated or deactivated when the Access Monitor program is started and stopped.

You must activate exit ICHPWX01 explicitly if you are using zSecure Audit by itself. In this case, activate the exit to process the additional SMF records that ICHPWX01 generates for all password change events. You can also activate the exit to apply maintenance changes to a module without having to IPL the system. Activation explicitly refreshes the exit.

The following table summarizes the supported exits and associated functions.

Table 280. Exits supported by the C2XACTV program

Exit	Function
ICHPWX01	ICHPWX01 is the RACF New Password exit that logs all password change events. This exit is included in zSecure to complement the RACF-generated, new password SMF records. For z/OS release 1.6 and earlier, RACF only logs password changes through the ALTUSER and PASSWORD commands. With the ICHPWX01 exit, RACF also logs password changes that occur through logon or signon events or through a JOB-statement in JCL. Use the ICHPWX01 exit to track all password changes during audit processing. zSecure Alert and Tivoli Compliance Insight Manager Enabler for z/OS use this exit. Typically, the C2XEXITS parameter controls the exit. The ICHPWX01 exit only writes an SMF record and does not change control blocks. However, if you have your own exit that does change control blocks. the changes might affect the contents of the SMF record.
ICHRDX02, ICHRCX02, ICHRFX04	RACF calls these exits in the following situations: • When the program runs AUTH or FASTAUTH commands during access verification. • When the program runs DEFINE commands during the process to create, update, or delete data sets and resource profiles. The Access Monitor program also uses these exits, automatically activating and deactivating them as needed. These exits do not affect regular processing; do not update control blocks, and do not add or modify SMF records.

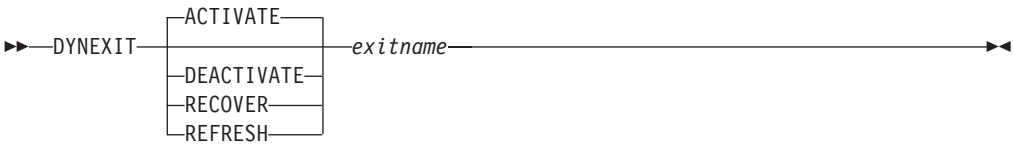
Use the following code sample to run the Exit Activator:

```
// JCLLIB ORDER=(MY.CKRPARM,CKR.SCKRPROC)
//  EXEC  C2RCACTV,CONFIG=MYCONFIG,PARM='DYNEXIT ACTIVATE ICHPWX01'
```

The zSecure RACF Exit Activator requires at least one of the following products: zSecure Admin, zSecure Audit for RACF, zSecure Alert for RACF or Tivoli Compliance Insight Manager Enabler for z/OS. zSecure Alert and Tivoli

Compliance Insight Manager Enabler for z/OS automatically establish the New Password exit automatically. However, you can run the DEACTIVATE command to turn it off.

The report data from the exit goes to the C2XPRINT DD statement. You can supply the commands for the RACF Exit Activator either on the PARM field or through a C2XIN DD statement. The RACF Exit Activator has the following syntax:



The following list describes the commands and parameters:

ACTIVATE turns on the RACF exit. If the currently installed exit is the one provided by the RACF Exit Activator program C2XACTV, the program issues an error message and stops.

The ACTIVATE command loads the Dynamic Exit Support routine and changes the RCVT pointer so that the routine is called by RACF. If another exit routine exists before C2XACTV runs, that exit routine is started as a Functional Exit Routine of C2X.ICHPWX01. If the RCVT pointer is zero–indicating that no exit point is in use–an exit point for C2X.ICHPWX01 is defined, but no Functional Exit Routine is installed.

exitname identifies the exit point you want to activate, deactivate, recover, or refresh. See Table 280 on page 694 for a list of supported exit points.

DEACTIVATE turns off the exit. If the ACTIVATE function replaced an existing RACF exit module, the original RACF exit module is reinstated during the deactivation process.

RECOVER removes the dynamically loaded exit routines from storage and restores the system to its previous state. You can only issue this command after the corresponding dynamic exit is de-activated. Use this command with extreme care. Programs that load the address for a RACF exit routine without checking whether the address is still valid might experience various abends after running the RECOVER command.

In most situations, you do not need the RECOVER command. Because the modules loaded into LPA by the C2XACTV program are typically less than 4K in size, removal is hardly ever required.

REFRESH determines whether the specified exitpoint is installed. If it is, zSecure refreshes all modules from the same source specified during the activation process. If the exitpoint is unavailable, zSecure creates an error message and exits the program. Existing Functional Exit Routines for C2X.ICHPWX01 might not be changed.

Additional exit routines are defined for pre- and post-processing Functional Exit Routine. These routines are independent of the REFRESH or ACTIVATE function, The exit routines provided by the C2XACTV program are loaded and linked to these pre- and post-processing exits.

For additional information about the RACF Exit Activator, see the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

Starting zSecure through line mode commands

To start programs from line mode, replace all DD statements except JOBLIB and STEPLIB with ALLOCATE commands (TSO) . You can start the program by typing the program name or program path (z/OS UNIX). You can specify the command manually or using a script. The ISPF interface is such a script.

CKRCARLA

You can start CKRCARLA directly from TSO, with semicolon-separated CARLa commands as parameters.

In addition, the version of CKR supplied with IBM Security zSecure accepts MODE(LINE) on its input. Your installer might have established installation-specific copies of CKR, perhaps under different names. For information, consult your installer. Use the default CKR program or installation-specific copies of this program to run the product in line mode.

If your site has a previously prepared data set member that contains your CARLa statements, use the following commands to run the commands in line mode:

```
ALLOC FILE(SYSIN) SHR REUSE DA('MY.CARLA(MEMBER1)')
%CKR MODE(LINE)
```

Note: You cannot supply line mode input from a terminal or use ALLOC FILE(SYSIN) DA(*). To process terminal input, do the following:

1. Create a script to generate the CARLa commands based on the terminal input data.
2. Write the CARLa commands to a data set.
3. Start the program and use the data set created in Step 2 to run the commands.

CKGRACF

In addition to the TSO CALL method, you can also call CKGRACF in line mode: Type the following CKGRACF command directly after the program name at the TSO READY prompt:

```
CKGRACF RDELETE FACILITY '*' DISCRETE
```

The CKGRACF program is only supported by zSecure Admin.

IBM Security zSecure JCL procedures

IBM Security zSecure provides a number of JCL procedures that can be customized for use in your environment. See the following topics for details:

- "C2RC and the naming convention for your data sets"
- "Other zSecure procedures" on page 697

C2RC and the naming convention for your data sets

The general purpose JCL procedure C2RC can be used to run the main zSecure program with the specified CARLa member from the SCKRCARL library. You can override the SYSIN DD-statement if your CARLa member is stored in another library. You can also use instream (DD * or DD DATA) CARLa statements. The C2RC procedure provides the following parameters:

MEMBER=
Specifies the pre-defined member to run.

ALLOCSMF=*n*
Determines whether to allocate SMF (`ALLOCSMF=1`) or run without allocating SMF (`ALLOCSMF=0`).

ALLOCCKF=*n*
Determines whether to allocate a `CKFREEZE` data set (`ALLOCCKF=1`) or run without allocating one (`ALLOCCKF=0`).

ALLOCUNL=*n*
Determines whether to allocate an UNLOAD data set (`ALLOCUNL=1`) or use the live RACF database (`ALLOCUNL=0`).

CKRCMD=*n*
Specifies the action for the file. Use 1 to allocate `CKRCMD`, 0 for `SYSOUT=*`.

DSTAT=OLD
Specifies the disposition for the `CKRCMD` file.

OPTCARLA=
Specifies any additional CARLa statements or settings.

This procedure, and several others, use several `INCLUDE`-members. To create the procedure, specify values for the following parameters: `ALLOCSMF`, `ALLOCCKF`, `ALLOCUNL`, and `CKRCMD`. These `INCLUDE`-members represent a naming convention for your `SMF`, `CKFREEZE`, `UNLOAD`, and `CKRCMD` data sets. If your naming conventions do not match the conventions in the shipped C2RI* members, create your own members with these names in a data set of your own. For example, create members in the data set where you store the configuration members and point to that data set with a `JCLLIB` statement. Possibly, your installer has created customized members in a standard procedure library on your system.

Other zSecure procedures

zSecure provides other JCL procedures for specialized tasks. Several of these procedures call the `C2RC` procedure. Due to a z/OS restriction, you cannot add or override DD statements on the `C2RC` job step when you start the outer procedure. If you must run any DD statement additions or overrides, call `C2RC` directly. For an example, see "Two-pass queries" on page 692.

Note: Your product data sets might not contain all the members documented in this topic. The members included depend on which products and product options are installed on the system.

The following procedures are provided with zSecure:

CKACTM, CKACTPRT, CKACTSRT, CKACTSYS
These procedures apply to the Change Tracking system. For details, see *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

C2EAUDIT, C2ECLSMF, C2ECSTOP
These procedures apply to the Agent for Tivoli Compliance Insight Manager Enabler for z/OS. For information, see the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

C2PACMON
Manages the Access Monitor function available in IBM Security zSecure Admin. The Access Monitor collects usage data on resource profiles and the authorizations defined within the profile. The data can be used to identify

unused or obsolete profiles and access permissions so they can be corrected or removed. For information about setting up the C2PACMON program, see *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*. For information about using it, see Chapter 10, "RACF Access Monitor," on page 643.

C2PCOLL, C2PCRECI, C2POLICE
These procedures apply to zSecure Alert. See the zSecure Alert User Reference Manual.

C2RCACTV
This procedure establishes the IBM Security zSecure RACF Exit Activator. For additional information, see the topic"Starting zSecure programs using JCL" on page 690 and the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

C2RCMSYN
For zSecure Admin, this synchronizes two RACF databases using merge. You must supply data set names for the two input parameters: `CORRECT` and `ONE2FIX`. These parameters represent two `UNLOAD` files. The program updates all profiles in ONE2FIX data set so they match the equivalent profiles in the CORRECT data set. The program uses a standard MERGE command to generate the RACF commands for adding missing profiles and updating existing ones. You run a separate process to generate the RACF commands to delete profiles from the ONE2FIX file that are not present in CORRECT file.

C2RCXCKG
Runs CKGRACF commands. Supply the commands through a `CKGIN` DD-statement.

C2RCXTSO
Runs RACF and CKGRACF commands that have been generated by IBM Security zSecure. For input, specify a data set that has been created by a previous job or step that runs procedure C2RC with `CKRCMD=1`. If your input comes from another location, override the `SYSTSIN` DD-statement.

C2RC2
A general two-phase CARLa procedure: The first job step writes the CARLa code to the DD-statement `CKR2PASS`. The second job step runs the code in the first job step. You can specify the following parameters:

MEMBER=
Specifies an existing member that includes the code to run.

ALLOCCKF=0
Determines whether to allocate a `CKFREEZE` file. Specify one `1` allocate the file. Specify `0` to run without allocating it.

ALLOCUNL=0
Determines whether to allocate an `UNLOAD` file for RACF. Specify one `1` allocate the file. Specify `0` for the live database.

CKRCMD=0
Determines whether to allocate a `CKRCMD` file. Specify one `1` allocate the file. Specify `0` to use SYSOUT=*.

OPTCARLA=
Specifies any additional CARLa statements to run.

C2RSERVE, C2RSLOG, C2RSTOP
These procedures are used with IBM Security zSecure Visual. See the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

IBM Security zSecure jobs

The SCKRSAMP data set in the product supplies a number of sample jobs. Before using the jobs, you must update the data set names and other parameter variables for your environment. For example, you must update jobs that include a print step to add the correct print destinations. Before you customize the jobs, copy them to your own data set. You need the original versions of the jobs in the SCKRSAMP library so that you can copy and customize them for use in different zSecure configurations. In addition, if the modified jobs are saved in the SCKRSAMP library future maintenance or upgrades might overwrite your customization because the SCKRSAMP library is SMP/E managed.

A partly customized copy of the SCKRSAMP library known as the CKRINST library is normally created during the installation process. For details, see *Installing the software* in the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*. If you deploy zSecure on multiple z/OS images, you might require more than one copy of the customized SCKRSAMP library for the different images.

Before using these jobs, customize them for your z/OS image and the specific department or organization that the job supports. Copy the job, and then update the data set names and parameter values. Specifically, check the jobs to determine whether they require any of the following updates:

- Most of the zSecure jobs contain a JCLLIB statement that specifies your configuration data set and the SCKRPROC data set. Verify that the data set names are the correct ones for your installation. Typically, the referenced data sets have been renamed or copied to a standard procedure library for your JES. For example, the configuration data set name is always unique to your organization.
- Many jobs also pass a specific zSecure configuration file name when calling a procedure. Make sure that the job specifies the correct configuration file for the context where the job is used.

The following list describes the zSecure sample jobs. Your product data sets might not contain all the members listed. The members included depend on which products and product options are installed on the system.

CKAJTCT1, CKAJTCT2, CKAJTCT3, CKAJTM, CKAJTSRT, CKAJTSYS
These jobs apply to the Change Tracking system. For additional information, see the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

C2AJFMBV
This procedure applies only to zSecure Audit for ACF2. The RACF version of this job is C2RJFMBV.

C2EJSTOP, C2EJSTRT
These procedures apply to the Tivoli Compliance Insight Manager Enabler for z/OS for the Tivoli Compliance Insight Manager or Tivoli Security Information and Event Manager. For details, see the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

C2PJRECI
This job applies only to zSecure Alert. See the *IBM Security zSecure Alert: User Reference Manual*.

C2RJ
Generates a collection of standard reports. To generate reports, uncomment the statements for the reports you need. See procedure C2RC for parameters.

C2RJFMBV
Report on violations per department through email. The following statements and parameters need site-specific customization:

OPTCARLA=option emt=*POSTMASTER@C2RCUSTD* Specify the email address of the person to receive the report bundles that did not get an email address through the EMAIL lookup data set. This address is also used for the email sender, but not for the reply-to address. The option parameter EMT is the abbreviation for ERRORMAILTO.

SMTPNODE= Specify the NJE node where SMTP runs with parameter.

SMTPOUT=B Change this value to the SYSOUT class for SMTP output.

EMAIL DD Change the inline ddname contents to contain the correct addresses

C2RJFUNL
Unloads and selects SMF records from live SMF data.

- You can customize this job to specify the SMF record types to be collected in the inline SYSIN data set.
- Add the specific number of your HSM functional statistics record rather than only specifying SETSYS SMF.
- Confirm that the /*JOBPARM S= and SYS= parameters specify the same system.

Note: If the first character of the system name is numeric, you must add an alphabetic character to the SYS= parameter to prevent invalid data set names.

C2RJMALL
Merges the profiles in an UNLOAD of a remote database into the current database. For details, see the Chapter 9, “Merge Usage Guide,” on page 623. Update the ALLOC statements before submitting the job.

C2RJMDIF
Merges the profiles from the active backup database into another database so it matches the live database. If merge conflicts occur, the profile data from the active backup database takes precedence. The output in CKRCMD consists of the commands to merge the profiles. For details, see the Chapter 9, “Merge Usage Guide,” on page 623. Be sure to adapt the ALLOC statements before submitting the job.

C2RJMGRP
This job shows how to merge group A into group B. In the job, the same database is used as source and as current database. Before using the job, make the following changes:

1. Adapt the ALLOC statements to suitable UNLOAD files.
2. Replace the occurrences of *A* and *B* on the X and MERGERULE statements by the names of the groups you want to merge.

C2RJMSYN
This job synchronizes two RACF databases using merge. Before using the job, review the following items and make any required changes:

Notes:

1. This job expects two UNLOAD files as input.
2. To use a database copy, Change the ALLOC statements for the various SYSIN files. You do not need to edit the PROC statement.
3. If you must run the job multiple times to complete the synchronization the process, change the DISP value for the output data sets on subsequent runs.

4. By default, the job sends all generated RACF commands to the same CKRCMD file. To send the commands to delete profiles to a different CKRCMD file, uncomment the DD statement at the bottom of the job and change the parameter values.

C2RJPREP
Create or refresh a CKFREEZE file, an UNLOAD file, or both. For more information, see the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

C2RJRSYN
Generates RACF commands to synchronize the RACF database with actual data sets present on a single volume. Specify the volume in the job.

C2RJSERV
This job applies to the zSecure Visual product. See the zSecure Visual Server Manual.

C2RJXCKG
See procedure C2RCXCKG.

C2RJXRFR
This CKGRACF daily job applies only toIBM Security zSecure Admin. See the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

C2RJXSAS
This job performs a pre-defined function on previously unloaded data to generate input for post-processing with SAS.

C2RJXTSO
See procedure C2RCXTSO.

C2RJ2
Generates a collection of reports requiring two-pass CARLa. To generate reports, uncomment the statements for the reports you need.

Supported file definitions for CKRCARLA

If redirection is not used, the following file definitions (FILEDEFs) are supported by the CKRCARLA program.

STEPLIB
STEPLIB or JOBLIB identifies the library containing the installed program.

SYSPRINT
Indicates the destination for listings and messages. This file type might require changing the settings to accommodate longer text lines (LRECL) and different record formats (RECFM).

LRECL The default logical record length does not support longer line lengths. The default relies on other DCB parameters to extend the text length to 132 when necessary. To support longer line lengths explicitly, change the default LRECL setting to a higher value. The maximum supported value is 32760.

RECFM (record format) supports the following values:

- **F** for fixed format
- **FB** for fixed-length, blocked
- **VB** for variable, blocked
- **FA** for fixed-length, ASA carriage-control characters
- **VA** for variable, ASA print-control characters

- **FBA** fixed, blocked, with ANSI carriage control characters
- **V** for variable format
- **VB** for variable, blocked
- **VBA** variable, blocked, with ANSI carriage control characters
- Record Format

The default record format is VBA. For 3800-type laser printers, you can add the OPTCD=J parameter to the DCB parameters in combination with the CHARS=(norm,bold) parameter. The value norm specifies the character set for normal text; bold specifies the character set for bold text.

The default block size is approximately half track if a full track is larger than 32 KB, and consistent with the LRECL and RECFM values.

SYSIN
File type for specifying the CARLa command input. For command documentation, see Chapter 12, "CARLa Command Language," on page 713. This file type supports a maximum LRECL of *32760* and supports both the RECFM=F(B) and RECFM=V(B) format settings.

SYSTERM
The SYSTERM file is an optional file that you can allocate to receive messages. This file receives messages issued in response to a return code of 12 or higher and a number of status messages. Issue one of the following commands to receive the messages on the screen:

- Under CMS, issue the following command: FILEDEF SYSTERM TERMINAL.
- Under TSO, issue the following command: ALLOC F(SYSTERM) DA(*).

CKRCARLA
The CARLa IMBED or INCLUDE statement use this ddname if the MEMBER was specified without a value for DDNAME.

C2REMAIL
Determines the destination of the following email commands: MAILTO and BUNDLEMAILTO. If you have not allocated this file, the SMTP (Simple Mail Transfer Protocol) settings are used to route email.

You can specify the email settings using the following keywords on the OPTION command SMTPWRITER, SMTPCLASS, and SMTPNJENODE. If you do not specify any keywords, the default values are in effect.

Use the following statement to allocate the C2REMAIL file directly to the email server:

```
SYSOUT=(outputclass,SMTP),DEST=&SMTPNODE
```

&SMTPNODE is the name of the JES2 or JES3 or RSCS node where SMTP is active.

SMTP is the writer-name of the installed SMTP. This value defaults to SMTP. However, the value might be different, depending on the installation path.

You can specify an LRECL value of 255 or higher. To support EBCDIC to HTML translation, specify an LRECL value that is 796 or higher. This value increases the line length up to six times the length of the original default length (132). Do not use RECFM=VBA or RECFM=VBM because they are not supported by all SMTP writers.

Alternatively, you can allocate this file to a data set to analyze the emails rather than sending them. You can reach the same result by allocating a C2RSMTP DD, and using the SMTPTOFILE command.

Note: The email function of Security zSecure is not intended to be used with the INFOPRINT email support introduced in z/OS V1R5.

C2RSMTP
File that receives redirected email when the SMTPTOFILE command is used. To support EBCDIC to HTML translation, specify an LRECL value that is 796 or higher. This value increases the line length up to six times the length of the original default length (132). Do not use RECFM=VBA or RECFM=VBM because they are not supported by all SMTP writers.

Use the following fields to build an email:

HELO
Required. Specifies an RFC2821 domain name. Make sure that reverse lookup of this name returns the sending IP address, otherwise mail might be refused. The domain name comes from the local host name returned by the TCP/IP stack GETHOSTNAME or GETHOSTBYNAME command. If this command fails, the program checks the following parameters in the order listed to obtain the first available domain name: SMTPMAILFROM, ERRORMAILTO, FROM, or REPLYTO.

RCPT TO
Required. Specifies an RFC2821 address for SMTP mail delivery. The value is constructed from the fields MAILTO, CC, and BCC.

MAIL FROM
Required. Specifies an RFC2821 address for SMTP routing of non-deliverable message notifications. The program determines the value by checking the following fields in the order listed and uses the first available address: SMTPMAILFROM, ERRORMAILTO, REPLYTO, or FROM.

From
Required. Specifies an RFC2822 address. The program determines the value by checking the following fields in the order listed and uses the first available address: FROM, SMTPMAILFROM, ERRORMAILTO, REPLYTO.

To
Generated field. Specifies an RFC2822 address. It is constructed from the MAILTO field.

CC
Optional. Specifies an RFC2822 address. It is constructed from the CC field.

BCC
An RFC2822 address. It is constructed from BCC. This field is optional.

C2RSNMP
File that receives the redirected output from SNMP when the SNMPTOFILE command is used. To support the line length for writing SNMP traps, specify the following values for the record format and line length: RECFM=VB,LRECL=1060

C2RSYSLG
File that receives the redirected output from the UNIX syslog when the OPTION SYSLOGTOFILE setting is specified. To support the line length for writing syslog traps, specify the following values for the record format and line length: RECFM=VB,LRECL=2048.

C2RWTO
File that receives the redirected output from the Writer to Operator (WTO) function when the WTOTOFILE command is issued.

CKRCMD
Optionally, you can allocate the CKRCMD file (implicit allocation mode only). This file receives the command output generated as result of COPY, MOVE, REMOVE, or VERIFY operations. Allocating the file implies that TSO commands must be generated where possible.

The default values for data control block (DCB) parameters are as follows:

LRECL
The default logical record length depends on the CKRCARLA execution environment. For batch jobs, the default record length is 255 bytes. For new users, the ISPF user interface allocates data sets with default settings of RECFM=FB and LRECL=80. To change the RECFM and LRECL settings, see "SE.0 Setup - Run Options" on page 1643. When sending output to a z/OS UNIX file, the default line length is 32752 bytes whether you execute CARLa commands as a batch job or run commands from the ISPF user interface.

RECFM

The default record format depends on the CKRCARLA execution environment. For batch jobs, the record format is variable length (VB). For new users, the ISPF user interface allocates data sets with a record format of fixed length (FB) as the default. To change the RECFM setting in the run options, see "SE.0 Setup - Run Options" on page 1643.

For VB records, the first 8 bytes of each line are blank because TSO EXEC program processing expects line numbers in these positions and ignores them. For fixed length (FB) records, the last 8 bytes are blank unless you have specified an overriding line length by using LL=*value*.

Block size

The block size defaults to half track if a full track is larger than 32 KB.You can run CKRCMD as a CLIST or pass the file to the Command Execution Utility (CKX).

For security reasons, make sure that erase-on-scratch is in effect for this data set.

CKRUNLOU
Unloads data from the specified data input sources. This optional file is used for UNLOAD operations.

If you are using IBM Security zSecure Admin, the UNLOAD operation is requested automatically when allocating the file.

CKRUNLIN
In implicit allocation mode, you have the option to allocate this file. If allocated, change the CKRUNLIN parameters to point to a file with a previously unloaded security database. No records are read from the current security database. See the comment on CKRUNLOU.

CKRACF01
Optionally, you can allocate this file to indicate where the RACF master data set or its backup copy can be found–only in implicit allocation mode. If you omit CKRACF01 and CKRUNLIN, the currently active primary RACF master data set is allocated dynamically along with other primary data sets for CKRACF*nn*.

CKRACFnn
If you allocate CKRACF01, you can also allocate CKRACF02 and up to indicate additional non-master RACF data sets or their backup or archive copies. If you omit CKRACF01 and the RACF database has more than one data set, the remaining currently active primary data sets or whatever else has been implied by an ALLOC command are automatically allocated.

SYSTCPD
This DD-statement might be necessary when you write reports in SMTP- or SNMP-format. This type of reporting requires TCP/IP communication and possibly, translation of domain names into IP addresses and reverse. Your IP-stack might have other ways to provide for this translation. Consult the IP configuration documentation for your system.

CKFREEZE
Optional. You can allocate this file to receive information about the following types of data gathered from the system using zSecure Collect (implicit allocation mode only): `VTOC`, `VVDS`, catalogs, `HSM` data, `DMS` data, `CA1` data, `PDS` directories, `UNIX` file system content, and so on.

The `CKFREEZE` file, or `CKRCKF0`*n*) is required for the following command processing:

- `VERIFY` options: `ONVOLUME`, `INDICATED`, `NONEMPTY`, `PROGRAM`, and `PGMEXIST`
- `REPORT` options: `DATASETS`, `AC1`, and `PADS`.

CKRCKF0-n
Optionally, you can allocate the files CKRCKF00 - CKRCKF09 instead of or in addition to the CKFREEZE file. Use these files to provide collected configuration data from multiple systems (implicit allocation mode only).

CKREPORT
If allocated, this file automatically receives the data from the `REPORT` command unless the `REPORT` command is preceded by an `OPTION` or `PRINT` command with a specified `DDNAME=`. In this situation, the data is written to the specified ddname rather than the `CKREPORT` file. For default settings, see `SYSPRINT`.

CKRSMFnn
Optionally, you can allocate the files `CKRSMF00 - CKRSMF99` instead of or in addition to SMF. Use these files to provide additional SMF input (implicit allocation mode only). Not used with IBM Security zSecure Admin.

<any input dd>
Specifies any ddname that is specified in an `INCLUDE` or `IMBED` statement.

<any output dd>
Specifies any ddname that is specified in the `DDNAME` parameter for the `OPTION` or `FILEOPTION` commands. Any `LRECL` and `RECFM` specifications on the JCL DD statement are honored. For a list of supported values and other considerations, see the SYSPRINT file definition.

If you do not specify values for `LRECL` or `RECFM`, zSecure determines them based on the type of data directed to the ddname. For `LRECL`, zSecure uses the largest effective `LINELENGTH` for any `NEWLIST` command directed to the output file. The program also considers other DCB parameters for writing lines of this length. The `LRECL` selected matches one of the following:

- An explicit `LINELENGTH` parameter for this ddname on one of the following statements or commands: `OPTION`, `FILEOPTION`, `BUNDLE`, or `NEWLIST`.
- The default `LINELENGTH`, which is 132 for a data set and 32752 for a UNIX file.

By default the record format (RECFM) of a data set is VBA. This default is only changed to VB if all NEWLIST commands for this ddname have specified NOPAGE directly on the NEWLIST statement or through one of the following commands: OPTION, BUNDLE or FILEOPTION.

CKR2PASS
This file is only written through the DDNAME parameter, as documented on the OPTION command. It has the same default characteristics as CKRCMD. It is intended for two-pass CARLa, as in the procedure C2RC2 and in the ISPF interface.

Using the scripts in the IBM Security zSecure CARLa library

Several CARLa scripts are supplied in the SCKRSAMP library. Most of these scripts are used by the ISPF interface and by IBM Security zSecure jobs and JCL-procedures.

Note: Your product data sets might not contain all the members documented in this topic. The members included depend on which products and product options are installed on the system.

Naming convention

As a first classification, the first three characters indicate the component or feature for which the script is intended:

Table 281. Product prefixes for CARLa scripts

Prefix	Component or feature
CKA	zSecure Audit for RACF
CKG	CKGRACF component IBM Security zSecure Admin
CKR	IBM Security zSecure Admin
C2A	zSecure Audit for ACF2
C2E	Tivoli Compliance Insight Manager Enabler for z/OS
C2P	zSecure Alert
C2R	zSecure Visual or zSecure Admin and Audit common
C2X	zSecure RACF Exit Activator

The fourth character represents the type of the script:

Table 282. Character indicating type of CARLa script

Type code	Use
D	Interactive display queries (some can also be used to produce batch reports).
L	Batch reports (not intended for interactive use).
R	Default layouts for CARLa REPORT commands (backwards compatibility)
S	Inclusion members with CARLa DEFINE statements for SMF or other logs
V	Verify commands.
X	Used from the Security zSecure ISPF interface.

Customizable CARLa scripts

Some CARLa scripts specify items like data sets and RACF groups with names that do not match the names in installation. You can customize these scripts to specify the correct names. However, do not customize the original members in the SCKRCARL data set. Because this library is managed by SMP/E, future maintenance might overwrite your customization. In addition, changing members within the shipped SCKRCARL data set would violate distributed-oriented installation conventions. To customize the scripts, create copies in a data set of your own, and use this data set concatenated in front of the shipped CARLa library.

For an individual user, you can specify the use of this local data set in the UPREFIX parameter in the IBM Security zSecure configuration. For a group of users the WPREFIX parameter is more appropriate. UPREFIX and WPREFIX are described in the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

Table 283 lists the CARLa scripts that you can customize.

Table 283. CARLa customizable scripts

Script	Customization
CKALFJOB	You might want to add a select statement to the SMFSEL NEWLIST to select specific users and then uncomment the NEWLIST. Alternatively, you can include the CARLa script after an earlier NEWLIST named SMFSEL.

CKRDPWIN
CKRLPWIN
	Creates reports that show user IDs that do not change their passwords often because they have an exceptionally long password interval. The interval can be long because the user profile has one of the following conditions:
	• An exceptionally long password interval
	• No password interval.
	• Can logon without a password.
	• Can log in with an OIDCARD.
	When you configure the report, you can customize the length of the password interval for selecting records by editing the PWINLONG NEWLIST. To keep the report manageable, exclude started task user IDs from these reports. If you have a special purpose group that your started task user IDs are connected to, you can exclude the name for the started task user group (stcgroup) in the select statements for PWINLONG and PWINNONE.
	Here is the select statement for PWINLONG:
	`select class=user`
	`segment=base`
	`passint>60 passint<255,`
	`congrpnm<>stcgroup`
	`/* exclude started tasks */`
	If you consider *exceptionally long* to be more than 30 and your started tasks are connected to a special STRTASK group, customize this statement as shown in the following example:
	`select class=user segment=base passint>30`
	`passint<255,`
	`congrpnm<>strtask /* exclude started tasks */`

CKRDPWNU CKRLPWNU CKRDLGNU CKRLLGNU	Specify the correct connect group name (congrpnm) to recognize started tasks in the WHERE clause of the DEFINE STCGROUP statement. The default group name is STCGROUP.

Table 283. CARLa customizable scripts (continued)

Script	Customization
CKRDPWXP CKRLPWXP	You must specify the correct connect group name (`congrpnm`) to recognize started tasks by in the select statement. The default is `STCGROUP`.
CKRD2DIF	Edit the data set names of `UNLOAD` data set to be used.
C2RXDEFU	As supplied with IBM Security zSecure, this member is empty. It is automatically embedded by `CKRXDEF1`. For batch processes that use the `C2RC` resource, this script behaves like the Setup (default) preamble option in the ISPF interface. Within the ISPF interface, the `CKRXDEF1` script and `C2RXDEFU` script are also automatically embedded in the product after the preamble. To perform local additions to the `CKRXDEF1` or `C2RXDEFU` scripts, do the following: • Create a copy`C2RXDEFU` in a data set that is identified by the configuration parameter `WPREFIX` or `UPREFIX`. See the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*. • To use this script in batch mode, override the procedure `C2RC` or change a local copy to concatenate `&WPREFIX..SCKRCARL` or `&UPREFIX..SCKRCARL` before `&CPREFIX..SCKRCARL`. In the ISPF interface the `WPREFIX` and `UPREFIX` data sets are concatenated automatically, if they exist.

Standard CARLa scripts

The following CARLa scripts are not intended to be customized. They are listed in the order in which they occur in the member list of the library, subdivided into ranges.

CKA* - zSecure Audit for ACF2
These members are part of zSecure Audit for RACF or common to zSecure Audit for ACF2 and zSecure Audit for RACF.

CKADF* - SMF displays
These members are SMF queries. See Chapter 7, “SMF and HTTP Reporting (Events menu),” on page 545.

CKADR* - RACF resource audit displays
These members are displays of AU.S - RACF resource. See Chapter 3, “RACF Audit Guide,” on page 255.

CKADU* - RACF user audit displays
CKADUTRU shows trusted users–users with sensitive access to the Trusted Computing Base. See “TRUSTUSR - Trusted users report” on page 292.

CKADVOLD - DASD volume protection display
CKADVOLD reports on DASD volume protection and sharing. See “DASDVOL - DASD volume report” on page 509.

CKAL$* - Concatenation members
These members include a number of other reports. See Chapter 5, “System Audit Guide,” on page 425 and Chapter 3, “RACF Audit Guide,” on page 255.

CKAL@* - Audit concerns for batch reports
These members are used to generate the **AU.S** audit concern OVERVIEW. They are not designed to be run separately, except CKAL@ALL, which generates the fullOVERVIEW

CKALR* - RACF resource audit batch reports
These members are print format reports of **AU.S - RACF resource**. See Chapter 3, "RACF Audit Guide," on page 255.

CKALU* - RACF user audit batch reports
`CKALUTRU` shows trusted users, that is, users with sensitive access to the Trusted Computing Base. `CKALUTR0` is the concise version of the same report. See "TRUSTUSR - Trusted users report" on page 292.

CKAS* - Field definitions for SMF and other log files
These members contain CARLa DEFINE and DEFTYPE statements to define the layout of fields or logs not supported internally. See "Field definitions for SMF and other log files" on page 590.

CKG* - CKGRACF scripts
These members are for use with CKGRACF, the authorized component of IBM Security zSecure Admin.

CKGX* - CKGRACF scripts
The following CARLa queries that generate CKGRACF command streams are available. These queries can be run with job C2RJXRFR, see "IBM Security zSecure jobs" on page 699:

Sample	Meaning
CKGXLIST	List profiles that require a `CKGRACF` refresh
CKGXREFR	Generate `CKGRACF REFRESH` commands for all profiles that require them
CKGXUSRW	Generate `CKGRACF WIPE` commands for `CKGRACF` data and user data for all applicable user profiles.

The other `CKGXR*` CARLa scripts support the `RECREATE` function. For information, see"R - Recreate a profile" on page 70.

CKRD* - zSecure Admin and Audit (or common) displays
`CKRDSY80` shows system settings and software levels. This script is documented in Chapter 5, "System Audit Guide," on page 425. The other CARLa scripts are documented in Chapter 3, "RACF Audit Guide," on page 255 and Chapter 2, "RACF Administration Guide," on page 51.

CKRL* - zSecure Admin and Audit (or common) batch scripts
`CKRL` is an empty member to prevent JCL errors for `CKRL`*variable* specifications, when the variable is empty.

CKRLSYSM (SMF system-wide settings), CKRLSY13, and CKRLSY80 (System settings and software levels) are documented in Chapter 5, "System Audit Guide," on page 425. The other CARLa scripts are documented in Chapter 3, "RACF Audit Guide," on page 255. CKRLGRPI, CKRLMTX1, CKRLMTX2, and CKRLSCPS are two-pass queries. To start two-pass queries use procedure C2RC2. The others documented there are one-pass queries. To start one-pass queries use procedure C2RC.

CKRR* - Report layouts
These members contain the original layouts for a number of `REPORT` command parameters to provide compatibility with previous versions of the product. If

you do not specify a different layout on a NEWLIST statement, these layouts are automatically embedded as the default layouts for a REPORT command.

CKRV* - Verify scripts

The following CARLa queries for resource analysis or one-time command generation are available.

Member	Meaning
CKRV	Empty member that prevents JCL errors for CKRV *variable* specifications, when the variable is empty.
CKRVDSN	Verifies the consistency and completeness of data set resource protection.
CKRVPROG	Verifies the consistency and referential integrity of program protection.
CKRVPWHC	Generates CKGRACF commands to convert hashed passwords to DES-encrypted passwords
CKRVRACF	Verifies RACF database consistency
CKRVTCB	List and check protection of Trusted Computing Base
CKRVUNIX	Generate RACF commands to populate the UNIXMAP class
CKRVWORM	Reports on globally writable resources, which are potential worm-holes.

CKRX* - Members used by the ISPF interface

The following SAS postprocessing sample is available for use with C2RJXSAS.

Member	Meaning
CKRXCFRQ	Lists connect counts to postprocess with SAS software.

The other CKRXC* members are part of COPY functionality. These are documented in "C - Copy" on page 55.

Member	Meaning
CKRXDEF1	A set of CARLa statements, which includes mostly DEFINE statements. Many CARLa scripts supplied with IBM Security zSecure, as well as the ISPF interface use this script. For example, the JCL procedure C2RC embeds the library in the procedure.

CKRXMCFS provides compatibility with earlier zSecure versions for the MENU command.

The CKRXR* members are part of RECREATE function. See "R - Recreate a profile" on page 70.

The CKRXW* members are configurations for zSecure Visual, the Windows interface for IBM Security zSecure Admin.

C2E* - Tivoli Compliance Insight Manager Enabler for z/OS

These members are used by the Tivoli Compliance Insight Manager Enabler for z/OS for the Tivoli Compliance Insight Manager. For details, see *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

C2RD* - zSecure Admin and Audit or common displays

C2RDFLD is for the FIELDS command. C2RDRAS and C2RDRASD are used to show RACF global settings (RA.S).

C2RL* - zSecure Admin and Audit common batch scripts
These scripts are used for UNLOAD.

C2RXDEF1
A set of CARLa statements, which contains mostly DEFINE statements. You can use these statements in many CARLa scripts supplied with IBM Security zSecure. The ISPF interface also uses these statements. For example, JCL procedure C2RC embeds it.

Other members in the SCKRCARL data set

The following members of the SCKRCARL library do not contain CARLa scripts:

CKA$INDX - Table of contents
Contains a list of all members in the CARLa library with a brief explanation.

CKA#ZA13
Release notes for zSecure Audit for RACF version 1.13

CKF#MSGS
zSecure Collect messages

CKG#MSGS
CKGRACF messages

CKR#MSGS
zSecure Admin and Audit messages

CKR#ZM13
Release notes for IBM Security zSecure Admin version 1.13

CKR#ZS13
Release notes for zSecure Admin and Audit version 1.13

CKR#Zz13
Release notes for zSecure Admin and Audit version 1.13

CKRL, CKRV
Empty members (to prevent JCL errors)

CKRXCFRS
Postprocess connects with SAS (see job C2RJXSAS)

CKX#MSGS
Messages for the CKX component of zSecure Admin and Audit

C2A#AA13
Release notes for zSecure Audit for ACF2

C2AI*
Control statements and messages for job C2AZJIVP. This job is used for Installation Verification.

C2P*
zSecure Alert messages and mappings

C2R#MSGS
zSecure Admin and Audit messages.

C2RX*
Miscellaneous use.

C2RXCSRT
SORT control statements used by Change Tracking.

C2RXLOG
Input for SCKRPROC C2RSLOG to copy server logs.

C2RXMHD*
Input for SCKRPROC CKACTM (email support).

C2RXSL01
XSLT stylesheet to transform tabular reports to HTML.

CKV#MSGS
Documentation of CKV messages.

Chapter 12. CARLa Command Language

The CARLa Auditing and Reporting Language (CARLa) is a programming language for creating RACF administration and audit reports using zSecure.

Choose from the following options to create, enter, and process CARLa commands:

Batch processing
For batch processing, you can specify CARLa commands in the `SYSIN` input file. You can also pass commands as parameters with the PARM keyword on the EXEC JCL statement. When called under TSO as a command processor, commands can be entered as TSO command parameters. For more information about using CARLa for batch processing, see Chapter 11, "Calling zSecure," on page 689.

Command-line processing
When zSecure is called as a command processor on VM/CMS, you can enter CARLa commands as VM command parameters. For more information about using CARLa for command-line processing, see Chapter 11, "Calling zSecure," on page 689.

ISPF interface

Under ISPF, the CARLa commands are typically generated by the panels. However there are several locations where you can specify your own custom CARLa:

- As an ISPF primary command CARLa.
- From the *xx*.C menu options such as EV.C, you can generate custom reports by specifying limited CARLa that is enhanced with some predefined layouts.
- The CO main menu option provides several possibilities for custom reporting. You can create and maintain your own custom reports and also create and submit single queries to create a one-time report.

`IMBED` and `INCLUDE` statements

Use the `IMBED` or `INCLUDE` command to read additional CARLa commands from files, data sets, or library members. CARLa cannot be used as input to the CKGRACF, the APF-authorized group-administration component. For more information, see Chapter 14, "CKGRACF Command Language," on page 1499.

For more information, see the following topics:

- "CARLa syntax"
- "CARLa command overview" on page 715
- "CARLa command reference" on page 717

CARLa syntax

This topic explains the syntax notation and rules for CARLa commands. It describes:

- The rules to follow when coding commands.
- How to read the notation for the command syntax

For more information, see the following topics:

- "Syntax rules"
- "CARLa syntax diagrams"

Syntax rules

Follow these rules when you code CARLa commands:

- Most commands are made up of a command keyword followed by parameters.
- Separate parameters by using blanks or commas.
- Use the equal sign (=) to assign a parameter a specific value.

  ```
  limit in=10000, out=10
  ```

- You can also specify a value by including the value in parentheses as follows:

  ```
  copy user(model) touser(newuser)
  ```

- For parameters that support it, specify a list of values using parentheses.

  ```
  report redundant, by=(reason, key)
  ```

- For statements that continue to the next line, follow the last parameter on the line with a comma.
- Commands intended for use in the program parameter string do not require parameters, `MARGINS` and `CAPS` for example.
- Use a semicolon at the end of the line to end the command, or use a new line character after the last parameter.

  ```
  select class=program; list memlst
  ```

- The command processor ignores blank spaces that are immediately followed by commas. It also ignores blank spaces on both sides of command keywords.
- Commands like `SELECT` and `SIMULATE` use the same format as the RACF and ACF2 command parameters where a value for a keyword is enclosed in parentheses:

  ```
  simulate setropts protectall(fail)
  select owner(sys1)
  ```

- Enter commands in any case.
- *Empty lines* can be part of a command, as implied by the previous definitions.
- You can specify commands in any order, except when using the `NEWLIST` command.

  This command divides the input into separate list descriptions. In each list description after a `NEWLIST` command, you must specify the selection and print commands (`SELECT`, `EXCLUDE`, and `PRINT`) before specifying any LIST or SORTLIST commands.
- For comment lines, use the `/*` symbols at the beginning of the line. Use the `*/` symbols to end the comment. If the comment crosses a line boundary, the command listing includes an * (asterisk) character behind the line number.

CARLa syntax diagrams

Table 284 describes the notations for the command syntax diagrams in the CARLa command documentation.

Table 284. Syntax notation for CARLa commands

Convention	Meaning
caps	Name of a command, keyword, or variable
italics	Value of a variable
Underlined	Default value

Table 284. Syntax notation for CARLa commands (continued)

Convention	Meaning
[]	Optional item.
{}	Pick one of the enclosed terms.
|	Pick only one of the separated terms.
...	Preceding value can be repeated.

CARLa command overview

Each time you run a command, you must specify at least one of the following main CARLa commands for processing the command output.

UNLOAD
Create a variable blocked copy of all selected records for later processing.

LIST
List the key (name) and optional fields or strings for all selected resources.

SORTLIST
Provides the same information as the LIST command, but the data is sorted in ascending order of the fields listed, with column headers.

DISPLAY
Like SORTLIST, but the data from the command is shown online in an ISPF table rather than being sent to a file. If you use batch mode or if the NEWLIST DISPLAYTOFILE parameter is set, it acts like the SORTLIST command.

(D)SUMMARY
Creates a report or ISPF table summarizing the values and counts of selected input occurrences.

VERIFY
Performs consistency checks on the command input and creates the RACF commands to fix any problems identified in the CKRCMD file.

REPORT
Report information that satisfies criteria not covered by the SELECT command.

(RE)MOVE
Creates RACF commands in the CKRCMD file to remove (or move) users, permits, or whatever is requested by the parameters.

COPY
To generate RACF commands on the CKRCMD file to clone users with their permits.

Use the following commands to select the information for auditing and reporting.

SELECT
To indicate conditions that the occurrence must satisfy to be selected. Multiple parameters on a single SELECT imply an AND function between the parameters - that is, all criteria must be satisfied to cause selection. Use of multiple SELECT statements implies an OR function - that is, any successful SELECT statement causes selection.

EXCLUDE
To indicate conditions that must be satisfied to reject the occurrence. Multiple parameters on a single EXCLUDE imply an AND function between the

parameters - that is, all criteria must be satisfied to cause rejection. Use of multiple EXCLUDE statements implies an OR function - that is, any of the EXCLUDEs matching is sufficient to reject the occurrence.

The following commands also influence the information processed.

ALLOC
To select a set of security databases and CKFREEZE, SMF, or command output files. If omitted, the default is the currently active security database and a small CKFREEZE subset of live control blocks called 'current settings'.

DEFTYPE
Create a custom NEWLIST type for reporting on any type of file.

LIMIT
Limit input, output, or processing to a maximum value. The value can be a number, a discrete or generic value for example.

SIMULATE
Answer what-if questions or provide information missing from the zSecure Collect file.

SUPPRESS
Suppress error messages for certain volumes, catalogs, users, or groups. You can also suppress command creation.

The following commands influence `SYSIN` and `SYSPRINT` characteristics.

CAPS
Force all output to uppercase.

Limitation:

DBCS characters in the output from a `NEWLIST` statement are not affected by the `CAPS` option if the corresponding NEWLIST statement also has a DBCS option specified. In all other cases, including a listing of the input commands, DBCS characters are not preserved.

MARGINS
Specifies which columns to read from `SYSIN`.

MERGELIST/ENDMERGE
Create a report containing several subreports, each with their own selection and format characteristics.

NEWLIST
Create more than one report or output file in one pass.

PRINT
Change print output file options like titles and page length.

A few examples:

```
select class=group, notermuacc
list class key
```

The following commands list all RACF groups with the NOTERMUACC attribute.

```
select operations or special
list class key
```

The following commands list all profiles with the OPERATIONS or SPECIAL attribute. Since no class is specified, both USER and CONNECT profiles are listed.

```
verify dataset protectall indicated
suppress volser=bckup1
suppress volser=bckup2
```

The following commands perform a cross-check of data sets with data set profiles, but excludes two volumes from its analysis.

The remainder of this section describes the syntax and parameters of all commands.

CARLa command reference

The CARLa command reference provides detailed information about each command including command and parameter descriptions, default settings, and any restrictions on a command.

Table 285. List of CARLA commands

ALLOCATE

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

Use the ALLOCATE command to select files or dynamically allocate existing data sets for input or output. You can abbreviate the command to ALLOC.

The ALLOC command provides an extensive set of parameters for selecting and allocating files or data sets. The parameters available depend on the command format and the allocation mode. The ALLOC command also provides global parameters that are available for use with any command format or allocation mode.

Syntactically, the ALLOC command has two formats, the *file* format and the *option* format. Specifying any file format ALLOC command activates explicit allocation mode. If you do not specify a file format command, the program activates implicit allocation mode, which is also the compatible with earlier versions.

File format

The file format explicitly defines one input or output file, data set, or live input source per command. The following example shows the syntax for an ALLOC file format command:

```
ALLOC TYPE=type
[DD=ddname] |
[DD=ddname {
  [DSN=dsn|dsn(mem) |
  CMSFILE='fn ft fm'} |
{ DSN=dsn|dsn(mem) |
  DSNPREF=prefix |
  CMSFILE='fn ft fm' |
  SMF |
  ACTIVE |
  [PRIMARY|BACKUP] [ACTIVE|INACTIVE] |
  [PATH='pathname'] |
  FILEDESC=n [PIPE=Y|YES]
  GETPROC=procedure   }
 [VOL=volser UNIT=unit]
 [SUBSYS=(name[.exit[.parm1[.parm2]]])
 [FUNCTION=MERGE|MAIN|BASE]
 [MOD]
 [FILEDATA=RECORD]
 [SVC99]
 [DELETE]
 [COMPLEX=complex]
 [VERSION=version-identifier]
 [NJENODE=nodename]
 [RRSFNODE=nodename]
 [ZSECSYS=system-name][ZSECNODE=node-name]
ALLOC TYPE=type
[DD=ddname {
 CMSFILE='fn ft fm' |
[PRIMARY] }
{
  CMSFILE='fn ft fm' |
  SMF |
 [PRIMARY]
```

```
    [FUNCTION=MERGE|MAIN|BASE]
   [COMPLEX=complex]
   [NJENODE=nodename]
[RRSFNODE=nodename]
```

Note: If the SMF keyword is used, the TYPE keyword can be omitted.

Option format

The *option* format has two kinds of parameters: the *ddname redirection* parameters and the *Live Input Source selectors* for live SMF files and live security databases. The *ddname redirection parameters* include parameters for files that require implicit allocation mode and parameters for files that are not dependent on the allocation mode.

The following example shows the live input source selectors (`SMF`, `LIVE`, `BACKUP`, `ACTIVE`, and `INACTIVE`).

```
ALLOC
[SMF]
[[BACKUP] [ACTIVE|INACTIVE]
  | DB=list
]
```

Global parameters valid with any format or allocation mode

This code sample shows the syntax for the global allocation parameters for any allocation command:

```
ALLOC [INDD=file] [OUTDD=file] [ERRDD=file]
[NOCLOSE]
[CLEANUP] [LETRAPOFF] [LETRAPON] [NOLE]
[NODCBE] [NOCLEANUP] [NODUMP] [NOESTAE]
[STORAGEGC] [TEXTPIPE=n] [NOBSAMBPAM]
[DDSAMPIN=file]
[DDUNLOUT=file] [DDCKR2PASS=file] [DDCKRTSPRT=file]
[CKRCMD_EXEC=EX|REQ|TSO]
```

For parameter descriptions, see "Implicit allocation mode parameters" on page 731 and"Global allocation parameters" on page 729.

The program uses the following default `ALLOC` parameters if no `CKRACF`*nn* files are allocated:

```
ALLOC PRIMARY ACTIVE
```

Usage notes

- If you specify any *file* format `ALLOC` command, *explicit allocation mode* is activated. If you do not specify a file format `ALLOC` command, *implicit allocation mode* is activated.
- Using the ALLOC parameters, the *file* format explicitly defines one input or output file, data set, or live input source per command.
- `ALLOC` commands are processed first, before any data is read and before the `NEWLIST` commands are processed.
- Not all allocation parameters apply to every product.
  - `SMF` and `DDPFXSMF` are for zSecure Audit.
- You can use the following parameters only in implicit allocation mode: `DDUNLIN`, `DDCKRCMD`, `DDPFXSMF`, and `DDPFXDB`. The following example, shows the syntax for these parameters.

```
ALLOC [DDUNLIN=file] [DDCKRCMD=file]
[DDPFXSMF=prefix] [DDPFXDB=prefix]
```

For more information about allocation modes and parameters, see the following topics.

- For file and data set allocation, see "Explicit allocation mode."
- "Global allocation parameters" on page 729
- "Live input source parameters" on page 727
- "Implicit allocation mode parameters" on page 731

Explicit allocation mode

Explicit allocation mode is the *file* format of the ALLOC command. Use the file format to specify one file or data set per ALLOC command and activate explicit allocation mode. Explicit allocation mode means that no files are implicitly allocated that can be allocated explicitly.

COMPLEX= *complex*

Specifies the security complex name. A complex is defined as a number of systems sharing the same physical security database. For example, a complex name can be used to distinguish OLD from NEW or PROD from TEST. The *complex* value can be a maximum of eight characters long.

The default complex name is based on information in CKFREEZE and UNLOAD data sets. Beginning with zSecure V1.12, the default value for COMPLEX is taken from the RRSFNODE name of the system. If the system is not running RRSF or if this information is not available, the default value is taken from the SYSPLEX name. If the SYSPLEX name has the value *LOCAL* or if this information is not available, the default value is taken from the SYSNAME.

Note: Whether the RRSF node name can be obtained, depends on whether a zSecure Server is active or not.

For UNLOAD data sets created using zSecure V1.11 and earlier, the data set contains the security data set names and an SMF SYSID. The security data set name is searched for in the CKFREEZE data with the same VERSION. If the name is found, the complex name is copied. If the name is not found, the system uses either a matching SMF SYSID name or the default system name. See the command DEFAULT.

Note: If a CKFREEZE file is not specified, a default in-storage source is assumed.

The logic used to assign the default complex name is documented in the SYSPRINT by messages in the CKR23*xx* range.

For output files, the names are assigned to complexes based on FUNCTION, and for the rest on a first-come first-served basis. See "FUNCTION" on page 722.

For input data set containing SMF records or Access Monitor records, the sequence of processing is different from that for other input sources. The SYSID is always first searched in the CKFREEZE sources, and each individual record is assigned to the matching COMPLEX. If the SYSID cannot be matched, a specified COMPLEX name is used. If no COMPLEX name has been specified, the SYSID is used as default for the COMPLEX.

DD= *file*
ddname=*file*

This keyword specifies the MVS ddname or CMS file definition for this allocation. Do not specify any reserved ddnames.

DELETE

Deletes the specified data set when processing ends. Processing ends when the

output processing for the TYPE has finished without an abend, attention key, or a return code of 12 or greater. The data set is only deleted if there is a NEWLIST TYPE= command for the specified type, or if there is another reason to read the data. The DELETE specification is implemented for MVS, but does nothing under CMS. The DELETE keyword is mutually exclusive with GETPROC. When the disposition for any file changes to DELETE, the program issues message CKR1357.

DSN= *dataset*
DA=*dataset*
DATASET=*dataset*
Specifies the data set name for dynamic allocation. Enclose the data set name in quotations. You can also include a member name in parentheses. If you omit the quotations, no user ID is prefixed to the data set name specified.

DSNPREF= *prefix*
Use this parameter to require a catalog search for selecting non-VSAM, VSAM cluster, and alias data set names starting with the indicated high-level qualifiers.

Syntax rules

- Do not specify quotations.
- The last qualifier specified is interpreted as a partial qualifier.
- You must specify at least TYPE= with DSNPREF=.
- DSNPREF= is mutually exclusive with the DD, UNIT, and VOLSER parameters.
- To match only full qualifiers, end the DSNPREF value with a period.
- When you specify TYPE=SMF for data sets for the same system, specify the data set names in alphabetic order and that the order matches the chronological order of the SMF records in the data sets. For the Tivoli Compliance Insight Manager Enabler for z/OS users, gaps in the SMF collection can occur if the order does not match.

Processing considerations

- Data sets are added as if ALLOC DSN= was specified with the same properties specified on the ALLOC DSNPREF= statement, unless the data set names are present on an explicit ALLOC DSN= with the same TYPE, FUNCTION, and COMPLEX, or previously added by such an ALLOC DSNPREF=.
- Any data sets found in the catalog are listed in a severity 0 message CKR1353.
- The absence of any matching data set names is not flagged. When both an alias name and the real data set name match with the prefix, the data set is processed twice.
- If no data sets are found, the program does not issue an error message. It continues to process other requests, if they exist. In this manner through repeated invocations of CKRCARLA, an unknown number of files can be processed for each interval, without sudden failures if the number happens to be 0 after some interval. If you specify the DSNPREF parameter, you cannot specify values for the UNIT and VOLUME fields.
- A maximum of 100 data sets can be automatically allocated per NEWLIST type per run. This restriction is due to the way the automatically allocated DDnames are constructed. When the DSNPREF specification finds more than 100 matches, the behavior depends on the NEWLIST type. For TYPE=SMF, a severity 8 message CKR1404 is given; the first 100 SMF files are processed, and any live SMF specification is ignored with a

CKR1405 message. For other NEWLIST types, a severity 12 message CKR1289 is given for any data set beyond 100 per type and the run is terminated. The behavior for TYPE=SMF makes it possible to use the DELETE operand on the ALLOC to remove processed SMF (staging) data sets and pick up the next 100 data sets in a subsequent run.

FILEDESC= *n*
Use this parameter to write an OUTPUT or CKRCMD file to a UNIX file descriptor, *n*. The file descriptor can be part of a pipe. The FILEDESC keyword is mutually exclusive with PATH, UNIT, VOL, and MEMBER.

FUNCTION= *function*
F=*function*

This keyword specifies how the allocated file is to be used. The main usage is when merging or comparing RACF databases or CKFREEZE files.

You can specify the following values for the FUNCTION keyword.

MAIN
For TYPE=RACF or TYPE=UNLOAD files, this value indicates that the database is to participate normally in NEWLIST TYPE=RACF and VERIFY/REPORT commands. This value is the default.

If two or more ALLOC statements specify the same COMPLEX but one has FUNCTION=BASE the other cannot have FUNCTION=MAIN.

MERGE
For TYPE=CKRCMD files, this value indicates that the file is to contain the commands to remove the profiles that have been merged into the current file. F=MERGE is only useful in IBM Security zSecure Admin.

BASE

Indicates that the specified input file is to be used as a baseline in a compare process. The FUNCTION=BASE specification is useful within the context of the following ALLOC types: RACF, UNLOAD, and CKFREEZE.

The use of FUNCTION=BASE is supported with the following Security zSecure entitlements: Admin, Audit, and Alert.

Creating the default COMPAREOPT specification:

To create a default comparison specification that is used when no other COMPAREOPT specification has been defined, use the following ALLOC command: ALLOC FUNCTION=BASE without including a complex name. When this statement runs, it establishes the system-defined COMPAREOPT specification named DEFAULT as the default comparison specification. The default COMPAREOPT is used in the NEWLIST and OPTION statements when no other COMPAREOPT specification is specified. For information about processing and restrictions, see "COMPAREOPT processing rules ."

For more detailed information about the Default COMPAREOPT specification, see "Compare processing" on page 46.

Processing rules
The following processing rules and restrictions apply to the ALLOC FUNCTION=BASE option.

ALLOC statement rules

- If two or more ALLOC statements specify FUNCTION=BASE, but use a different complex name, an error message is issued. After parsing the input commands, the processing is stopped.

- If two or more ALLOC statements specify the same COMPLEX and one includes the FUNCTION=BASE parameter, the other statement cannot include the FUNCTION=MAIN option.
- If a TYPE=CKFREEZE NEWLIST is specified with the FUNCTION=BASE option, then the ALLOC statement for the security database of the matching complex must also specify that option. If the option is not specified in both ALLOC statements, an error message is issued.

Establishing default settings for the COMPAREOPT statement

- The statement ALLOC COMPLEX FUNCTION=BASE establishes the default COMPAREOPT specification for the BASE keyword for the COMPAREOPT statement. That is, COMPAREOPT BASE=DEFAULT.
- The statement ALLOC FUNCTION=BASE establishes the default COMPAREOPT specification for *all* NEWLISTs and OPTION statements. That is, if any NEWLIST or OPTION statement requests a compare operation without specifying a COMPAREOPT, the system uses the DEFAULT COMPAREOPT.

  If a NEWLIST or OPTION statement specifies a compare operation without including a COMPAREOPT specification, and the DEFAULT compare specification has not been established, an error message is issued.
- The DEFAULT COMPAREOPT specification is not supported on the following NEWLIST types:
  - ACCESS
  - DASDVOL
  - FIELD
  - FIELD_OVERRIDE
  - MERGE
  - NEWLIST
  - REPORT types: REPORT, REPORT_AC1, REPORT_NONDEFAULT,REPORT_OUTOFGROUP, REPORT_PADS,REPORT_PROFILE, REPORT_REDUNDANCY, REPORT_SCOPE, REPORT_SENSITIVE
  - SMF
  - TEMPLATE
  - TYPE

  You can still perform compare operations on these NEWLIST types, but you must explicitly specify the COMPAREOPT statement.

  If you specify ALLOC FUNCTION=BASE, the display or report output contains information from all relevant input sources. However, for the NEWLIST types that do not support compare processing, the COMPARE_CHANGES or COMPARE_RESULT fields are reported as missing. Although these NEWLISTs do not support the default COMPAREOPT specification, you can use an explicit COMPAREOPT statement to do a comparison.

FILEDATA=RECORD

Opens the UNIX file, specified by PATH='*pathname*', as a record file. A record file is a binary UNIX file consisting of a number of records, each preceded by a 4-byte word specifying the length of the record. Using the FILEDATA=RECORD parameter, DEFTYPE files can be opened for input of records and TYPE=OUTPUT files can be opened for output of records.

When zSecure opens a UNIX file to read or write a RACF database unload, SMF unload, or CKFREEZE structure, the FILEDATA=RECORD parameter is not required. zSecure assumes that UNLOAD and CKFREEZE files are always in the record format.

z/OS V1.12 and later supports UNIX record type files. For UNIX record type files on these z/OS versions, the FILEDATA=RECORD parameter on the ALLOC command is not required because zSecure opens them as record files even if the ALLOC FILEDATA=RECORD parameter is not specified. For TYPE=OUTPUT files on z/OS V1.12 and later, you must always specify the FILEDATA=RECORD parameter on the ALLOC command in order for zSecure to open them as record files.

For z/OS 1.12 and later, it is possible to specify FILEDATA=RECORD files by using DD statements in JCL. When FILEDATA=RECORD files are specified in JCL, CARLa does not support reading or writing records that exceed 32760 bytes. To support FILEDATA=RECORD records that exceed 32760 bytes, specify FILEDATA=RECORD files by using ALLOC statements in CARLa instead of DD statements in JCL.

z/OS V1.11 and earlier versions do not support UNIX record type files. For UNIX files on these earlier versions, always specify FILEDATA=RECORD files by using ALLOC statements in CARLa instead of DD statements in JCL. For z/OS V1.11 and earlier, to open a DEFTYPE or TYPE=OUTPUT file in FILEDATA=RECORD format always specify the FILEDATA=RECORD parameter on the CARLa ALLOC statement.

GETPROC= *procedure*
Specifies the name of an external module for supplying the data for this type. The maximum length of the module name is eight characters. This keyword is intended for internal use only.

MOD
Appends output to an existing data set or z/OS UNIX file. The `MOD` keyword is only valid for non-partitioned data sets of `TYPE=CKRCMD` and `TYPE=OUTPUT`. It is only effective when used in combination with the `DSN=` or `PATH=` parameter.

NJENODE= *complex*
Specifies the name for the NJE node where jobs with commands should be sent. The name can be up to eight characters long. If you use `CKFREEZE` files, you do not need to specify the `NJENODE` because the `CKFREEZE` files contain the node information. However, the node information might be missing if there is a JES release support problem.

PATH= *pathname*
Specifies the z/OS UNIX path name. This keyword is an alternative for `DSN=` and `CMSFILE=`. The maximum path name length supported is 1023. When you specify this parameter with the `SVC 99` parameter, only the first 255 bytes of the path name are used; relative path names are not supported.

PIPE=YES
Use this keyword with `FILEDESC=`*n* to indicate that the output file descriptor must be explicitly closed. If this keyword is not specified for pipes, the other side of the pipe continues waiting on the pipe.

RRSFNODE=*node-name*
The name of the RACF remote sharing node where commands can be sent. The maximum length of the `node-name` is eight characters. You can leave this parameter blank if `CKFREEZE` files are used. This parameter is not currently in use.

VERSION

This keyword is used to classify the data allocated into separate sets such as OLD and NEW. The maximum length of the version identifier is four characters. This value is different from the COMPLEX value. The COMPLEX value is used to identify the systems that have a shared RACF database and that are the source of the data. You can use the VERSION specification to analyze data in the same COMPLEX at multiple points in time.

The VERSION keyword influences how CKFREEZE and security sources are grouped together into complexes. Generally, different VERSIONs are handled as separate complexes. A separate VERSION causes the old and new versions of a physical DASD volume to be interpreted as different volumes based on the point in time when the data is analyzed. A separate VERSION also causes RRSF sysplexes to be treated as different sysplexes even though the RRSF node names are the same. However, if you want to perform point-in-time analysis, use a different name for the COMPLEX even if you specify a VERSION. Many reports only show 8 characters of the complex name which does not include the VERSION identifier. If you use the same COMPLEX name, you cannot use the report to identify the data from different versions. If you write your own CARLa program for generating the report, the VERSION is shown in the report output if you specify an output length modifier of 13 or greater on the COMPLEX field. See "Modifying output length" on page 797.

ZSECNODE=*node-name*

Specifies the node name for locating the specified data set. The maximum length of the *node-name* is eight characters. This value corresponds to the node name specified in the network configuration file. The *node-name* specification applies to a RACF database that is shared between multiple systems. When using the ZSECNODE parameter, zSecure uses the preferred server that is designated in the zSecure configuration file to access the specified data set. The special value asterisk (*) specifies that all defined ZSECNODEs are used. The special value period (.) specifies that the current ZSECNODE is used.

If both ZSECSYS and ZSECNODE are specified, zSecure verifies that the specified system is defined as a member of the specified node. If the specified system is not a member of the specified node, zSecure issues an error message and the program stops.

Note: Sensitive fields that are present in UNLOAD data are not sent across the zSecure network.

ZSECSYS=*system-name*

Specifies the system name for locating the specified data set. The maximum length of the system-name is eight characters. This value corresponds to the system name specified in the network configuration file. The system name specification applies mainly to system-specific data sets like a CKFREEZE or an SMF data set, but it can also be used for a RACF database. zSecure locates the specified data set using the server on the specified system.

The special value asterisk (*) specifies that all defined ZSECSYS systems are used. The special value period (.) specifies that the current ZSECSYS is used. If both ZSECSYS and ZSECNODE are specified, zSecure verifies that the specified system is defined as member of the specified node. If the specified system is not a member of the specified node, zSecure issues an error message and the program stops.

SUBSYS=(*name***[,***exit***[,***parm1***[,***parm2*

Directs the allocation to the subsystem specified in the first positional

subparameter. The *name* has a maximum of four characters. The syntax for the rest of the subparameters depends on the subsystem.

Usage notes

- The syntax is like that of the SUBSYS parameter on the JCL DD statement. The maximum length of the subparameters supported is 67. You can specify the subparameters enclosed in three types of quotations. Quotations are required when a subparameter uses parentheses, commas, equal signs, or blank characters. By default the subparameters are passed to DYNALLOC as is, without changing the case. To avoid an IKJ5623I error, check that the subparameters are supplied in the correct case.
- For the LOGR subsystem, the second subparameter is an exit name, IFASEXIT for SMF log streams for example. The syntax for the rest of the subparameters can be found in the *z/OS MVS JCL Reference*.
- zSecure recognizes the LOGR subsystem and converts all subparameters to uppercase before supplying them to DYNALLOC.
- The DSN= parameter can be used to pass the log stream name.
- You must have READ access on the stream name specified in SAF class LOGSTRM. Otherwise, the system abends with a 913-74 error.
- SMF NEWLIST supports reading from SMF log streams.

SVC99

Request DYNALLOC (SVC99) and QSAM/BSAM I/O simulation instead of using more efficient UNIX open/close and direct UNIX I/O. You only need this parameter if the ddname is for passing to other components and you want an EBCDIC file.

If you use ENCODING=UTF-8 on an SVC99 allocated UNIX file, you get an unusable file because QSAM I/O emulation writes EBCDIC newline characters (X'15') between the UTF-8 records.

TYPE= *type*

Specifies the file or data set type to allocate. The following types are supported:

Table 286. File types for allocating data sources for zSecure

TYPE	Description
ACCESS	Type for allocating a data set for Access Monitor records from the RACF database cleanup function in zSecure Admin. This file is used by the ACCESS NEWLIST, and RACF_ACCESS NEWLIST. For details, see "ACCESS: Access Monitor Records" on page 953.
ACF2RULE ACF2INFO ACF2LID ACF2	
CKFREEZE	Type for allocating a data set to capture the zSecure Collect data required for RACF administration and auditing using zSecure.
CKRCMD	File type for generated commands created as a result of COPY, MOVE, REMOVE, or VERIFY operations.
DEFTYPE TYPE=*type*	You can use the DEFTYPE command for defining NEWLIST type for custom reports. For more information, see "DEFTYPE" on page 777.

Table 286. File types for allocating data sources for zSecure (continued)

TYPE	Description
INPUT OUTPUT	Use these types for general allocation of files for purposes like providing DD=CKRCARLA input or an output file for z/OS Unix that receives the data from a NEWLIST DD= statement. Use these file types with the DD= parameter to immediately allocate the file. If you do not specify the DD= parameter, the file is allocated later and cannot be used IMBED command processing.
RACF	Use this specification to allocate a RACF database. The database can be the RACF database of the system your job is running under (ACTIVE, PRIMARY, or BACKUP), a copy of the database, or of a foreign database that is in use by another z/OS or z/VM image (or by multiple images). For foreign databases and database copies, combine TYPE=RACF with a specification of the DATASET. In order to allocate a RACF database that consists of multiple data sets, specify multiple TYPE=RACF allocations for a single complex in the same order as the data set names occur in RACF data set name table ICHRDSNT. See "RACFDSN - RACF Data Set Name Table ICHRDSNT" on page 275. Note that allocating a RACF database incurs the risk that the database can be updated while zSecure is reading the database. To avoid this risk, use an UNLOAD data set.
SMF,SMFSTREAM	Use TYPE=SMFSTREAM for allocating an SMF log stream. This file is for SMF NEWLIST processing. You cannot specify parameters to limit the number of returned SMF records. If you must specify a limit, use TYPE=SMF with the SUBSYS keyword.
UNLOAD	Use TYPE=UNLOAD for allocating the file that stores the unloaded RACF data read from the live RACF database. During the unload process, zSecure copies the data to the UNLOAD file in a proprietary format suitable for high-speed searches.

In previous releases, TYPE=IOCONFIG is an alias for TYPE=CKFREEZE. TYPE=CMDOUT is an alias for TYPE=CKRCMD. TYPE=CKRUNL is an alias for TYPE=UNLOAD. Messages and explanations generally use the latter names.

UNIT= *unitname*
U=*unitname*
Unit name to use in combination with the volume serial to indicate the device where the data is stored. You must specify this parameter with the VOLUME.

V= *volume*
VOL=*volume*
VOLSER=*volume*
Volume to use in the dynamic allocation request. You must specify this parameter with the UNIT parameter with the volume serial.

Live input source parameters

ACTIVE
Use this parameter to select active (live) data as the data source for zSecure. ACTIVE is the default setting. You can use this parameter in both implicit allocation mode and explicit allocation mode. For zSecure Admin for RACF and zSecure Audit for ACF2, the following file types are valid: TYPE=RACF, TYPE=CKFREEZE, and TYPE=SMF.

For zSecure Audit for Top Secret, the following file types are valid: TYPE=CKFREEZE and TYPE=SMF.

For TYPE=SMF, the processing depends on whether SMF is recording to data sets or to log streams. If logging is done through data sets, all SMF recording data sets are allocated. If logging is done through log streams, all currently active SMF log streams are allocated. The SMF log stream file allocation sets the parameters DURATION=(24,HOURS), and SID(*name*) where *name* is the SMF ID of the current system.

The program must be able to find the specified log stream names. The log stream names can be located if you call the program in APF mode–through CKRCARLX for example, or if you connect to a recent CKFREEZE file with the specified SMF log stream settings. The CKFREEZE file must be part of the default complex.

Note: The SMF recording data sets or SMF log streams are only allocated if you specify an SMF NEWLIST.

BACKUP
Use this keyword to select the live backup database as input. Using BACKUP instead of ACTIVE can be used to reduce the I/O load on the primary security database.

DB= *n*
DB=(1,*n***,...) DATABASE=...**
Selects the RACF database sequence numbers. You must include sequence Number 1 for the master data set. The DB parameter must return number or a list of numbers. The highest number supported is 64. A maximum of 64 numbers can be combined in one run. The database sequence numbers are defined in the database name table, see the NEWLIST TYPE=DSNT. You can only specify the DB parameter on an ALLOC command in implicit allocation mode.

INACTIVE

Selects an inactive security database from the live system as the data source.

PRIMARY
PRIM
Selects the live data as the data source for zSecure. In implicit allocation mode, PRIMARY is the default data source selection.

SMF

Allocate SMF to allocate the live data source.

If SMF logging is being done to files or data sets, the SMF recording data sets are allocated, typically SYS1.MANx for example.

If logging is done through log streams, all currently active SMF log streams are allocated with the parameters DURATION=(24,HOURS) and SID(*name*). The *name* is the SMF ID of the current system. The program must be able to find the log stream names by either calling the program in APF mode through CKRCARLX for example, or by connecting a recent CKFREEZE file with the SMF log stream settings. The CKFREEZE file must be part of the default complex.

Note: The SMF files are only allocated if you specify a NEWLIST TYPE=SMF statement.

In implicit allocation mode, any SMF file previously allocated to ddnames SMF00–SMF09 is freed if the ddname is reused for a live SMF data set. SMF files

previously allocated to ddnames SMF or SMF10 and up, are not freed. The allocated data sets are used by zSecure Audit for ACF2. You can have gaps in the range SMF00–SMF09, but no gaps in the range SMF10 and up. For example, if you allocate SMF03, SMF05, SMF10, SMF11, and SMF15, the program does not process the SMF15 ddname.

In explicit allocation mode, specifying TYPE=SMF is equivalent to TYPE=SMF ACTIVE. The program does not use any data sets other than the SMF data set explicitly specified on an ALLOC command and the live SMF data source implied by this operand.

You can combine the Live input source parameters to select the data sets for the SMF data source.

Global allocation parameters

CKRCMD_EXEC= *target*
CMDOUT_EXEC= *target*
This parameter sets the target for commands written in CKRCMD. It can be TSO, EX, or REQ. The default is TSO. There is no separate target string for CKX, because this program is compatible with TSO. If EX is selected, RACF and IDCAMS commands are prefixed with CMD EX. If REQ is selected, RACF and IDCAMS commands are prefixed by CMD REQ. However, not all commands are supported by CKGRACF CMD REQ. This parameter is honored for all commands that are written to CKRCMD and accompanied by a message (as the result of a CARLa command). It does not apply to action commands under ISPF that can queue commands to CKRCMD.

CLEANUP
Forces an unconditional abend intercept and storage cleanup even though not running under ISPF. It is mutually exclusive with NOCLEANUP. The abend intercept is activated after the main input parse is complete. This behavior is in contrast to the default abend intercept cleanup behavior for ISPF which is activated before the main input parse. The intercept stops before the runtime system stops.

DDCARLA= *ddname*
DDSAMPIN= *ddname*
The *ddname* to be used as the default file for embedding members. It overrides CKRCARLA.

DDCKR2PASS= *ddname*
DDCNROUT= *ddname*
The *ddname* for queued CARLa command output. That is, CARLa commands that have been queued by line commands. If a ddname is specified by the DDCKR2PASS= parameter, the value overrides the ddname specified in the CKR2PASS parameter that is used otherwise.

DDCKRTSPRT= *ddname*
DDCNXOUT= *ddname*
The *ddname* to receive command output from TSO commands called by Security zSecure. If specified, this parameter overrides the CKXT@PRT ddname used otherwise.

DDUNLOUT= *ddname*
The *ddname* to be used as the target for unloading a security database. If specified, this parameter overrides the CKRUNLOU ddname used by default.

ERRDD= *ddname*
Redirects the SYSTERM to the specified *ddname*. You can use this parameter only on the PARM string. You cannot use it as a command in an input file.

INDD= *ddname*
Redirects the SYSIN file to the specified *ddname*. You can use this parameter only on the PARM string. You cannot use it as a command in an input file.

LETRAPOFF
This parameter is only valid on the PARM string. It can be used to turn off the Language Environment abend trap for diagnostic purposes. If NOLE has also been specified, this parameter is ignored. This parameter takes precedence over LETRAPON. If LETRAPON is also specified, it is ignored. Use this parameter only at the request of IBM software support.

LETRAPON
This parameter is only valid on the PARM string. It turns on the Language Environment abend trap for diagnostic purposes. If you also specify the LETRAPOPFF or NOLE parameters, this parameter is ignored. Use this parameter only at the request of IBM software support.

NOBSAMBPAM
This parameter is only valid on the PARM string. It can be used to disable use of the BSAM and BPAM access methods by the program–the program uses QSAM instead. Use of this parameter is only intended for use at the request of IBM software support.

NOCLEANUP
This parameter is only valid on the PARM string. It passes on debugging purposes to pass on abends to ISPF instead of recovering from them. It is meant to be used at the direction of IBM software support if the attempt to clean up the abend causes additional errors. You can find this option in the ISPF interface under SETUP TRACE as: Pass abends to ISPF.

NOCLOSE
Prevents the closing and freeing of data sets during abend recovery processing. You can specify this parameter in the parameter string (the PARM keyword in JCL). Use of this parameter is only intended for use at the request of IBM software support. You can find this option in the ISPF interface under SETUP TRACE as: Prevent closing/freeing data sets during abend recovery.

NODCBE
Prevents 31 bit mode from being used for file I/O processing. You can specify this value in the parameter string (the PARM keyword in JCL). Do not use this parameter unless IBM software support asks you to do so.

NODUMP
Suppresses a system dump. This parameter is only valid on the PARM string. Do not use this parameter unless IBM software support asks you to do so.

NOESTAE
Use this parameter to suppress error traps during the debugging process. This parameter is only valid on the PARM string. Using this parameter can cause Security zSecure to stop working. You can specify this parameter on the PARM. You can also set the option from the Setup Trace menu in the product by selecting **Suppress error traps**.

NOLE
Use this option to turn off Language Environment processing. This parameter is only valid on the PARM string. If this parameter has been specified, the

parameters LETRAPON and LETRAPOFF are ignored. You cannot send SNMP traps if Language Environment processing is turned off.

OUTDD= *ddname*
This parameter can be specified in the parameter string (the PARM keyword in JCL) to redirect SYSPRINT to the specified *ddname*. The parameter cannot be used with an input file.

STORAGEGC
This parameter is valid on the PARM string only. It can be used to turn on garbage collection during the run. In some cases, this setting reduces storage consumption but increases CPU usage.

TEXTPIPE= *n*
Sends all remote text files through a UNIX pipe. This parameter is only valid on the PARM string.

Implicit allocation mode parameters

DDPFXDB= *prefix*
Specifies the prefix for RACF input ddnames. It overrides the default CKRACF. You can specify a prefix of up to six characters. RACF input is read from *prefixnn*, where *nn* is a value in the range 01 – 64, inclusive. The prefix is only used in implicit allocation mode.

DDPFXSMF= *prefix*
Specifies the prefix for SMF input ddnames. It overrides the default SMF. The prefix value can have up to six characters. SMF input is from files *prefix* and *prefixnn*, where *nn* is a value in the range 00 – 99, inclusive. The prefix is only used in implicit allocation mode.

DDCKRCMD= *ddname*
DDCKRCMDOUT= *ddname*
The DDCKRCMD and DDCKRCMDOUT fields contain the ddname parameters for TSO or RACF command output. The ddname values can be generated by COPY, MOVE, REMOVE, and VERIFY operations. If specified, the DDCKRCMD value overrides the CKRCMD file for all NEWLIST commands that produce output for CKRCMD. A NEWLIST statement with F=CKRCMD also writes that output to the specified ddname. The file is read only in implicit allocation mode and applies only to the first security complex.

DDUNLIN= *ddname*
Specifies the *ddname* of the unloaded database for the zSecure data source. The value overrides the value specified in CKRUNLIN program. The file is only read in implicit allocation mode.

If you are uncertain what the resulting allocation would be, review message CKR0615 from the IN.M function on the product menu. This message shows the way that files are assumed to be connected to complexes.

Example - allocate live SMF

The SMF parameter is used with the SMF NEWLIST to allocate the live MVS data sets (usually SYS1.MANx) to SMF ddnames SMF00 and up. The use of this parameter is shown in the following example:

```
/* Allocate live SMF data sets */
alloc smf
```

Example - allocating and limiting an SMF log stream

The following example illustrates how to read SMF records from Oct 15, 2007 for system MYST from an SMF log stream:

```
alloc type=smf dsn=IFASMF.MAIN,
 subsys=(LOGR,IFASEXIT,'FROM=(2007/288),TO=(2007/288),LOCAL',
 'SID(MYST)')
```

Example - use back-up RACF data sets

To minimize impact on system operation, one might read the backup database instead of the primary. For most purposes except statistics, the information in the backup is identical to the primary. Use the following command to read the backup database.

```
alloc backup
```

Example - allocations for combined reports

To report with NEWLIST TYPE=RACF on SYS2 and SYS1 specify the following commands.

```
ALLOC TYPE=UNLOAD   DSN=my.SYS1.UNLOAD
ALLOC TYPE=CKFREEZE DSN=my.SYS1.CKFREEZE
ALLOC TYPE=UNLOAD   DSN=my.SYS2.UNLOAD
ALLOC TYPE=CKFREEZE DSN=my.SYS2.CKFREEZE
```

Note: COMPLEX parameters are not needed if matched UNLOAD and CKFREEZE files are used.

Example - allocations with RACF databases

You must use the COMPLEX parameter to create RACF reports (NEWLIST TYPE=RACF) on SYS2 and SYS1 using RACF database copies:

```
ALLOC TYPE=CKFREEZE DSN=my.SYS1.CKFREEZE
ALLOC TYPE=RACF     DSN=my.SYS1.RACFDB   COMPLEX=SYS1
ALLOC TYPE=CKFREEZE DSN=my.SYS2.CKFREEZE
ALLOC TYPE=RACF     DSN=my.SYS2.RACFDB   COMPLEX=SYS2
```

Example - allocations for compare

To create RACF reports (NEWLIST TYPE=RACF) for different snapshots of a system (SYS1), specify the following commands. In this example, the COMPLEX parameter is required because the UNLOAD and CKFREEZE files are all from the same system. Without the COMPLEX parameter, the program only processes two of the four files.

```
ALLOC TYPE=UNLOAD   DSN=my.SYS1.UNLOAD(-1)     COMPLEX=LASTWEEK
ALLOC TYPE=CKFREEZE DSN=my.SYS1.CKFREEZE(-1)   COMPLEX=LASTWEEK
ALLOC TYPE=UNLOAD   DSN=my.SYS1.UNLOAD(0)      COMPLEX=THISWEEK
ALLOC TYPE=CKFREEZE DSN=my.SYS1.CKFREEZE(0)    COMPLEX=THISWEEK
```

Note: COMPLEX parameters are now required because the system names are the same for all complexes.

Example - allocations for merge

To merge SYS2 into SYS1 specify the following commands.

```
ALLOC TYPE=UNLOAD   DSN=my.SYS1.UNLOAD
ALLOC TYPE=CKFREEZE DSN=my.SYS1.CKFREEZE
ALLOC TYPE=CKRCMD   DSN=my.SYS1.CKRCMD
```

```
ALLOC TYPE=UNLOAD   DSN=my.SYS2.UNLOAD FUNCTION=MERGE
ALLOC TYPE=CKFREEZE DSN=my.SYS2.CKFREEZE
ALLOC TYPE=CKRCMD   DSN=my.SYS2.CKRCMD FUNCTION=MERGE
```

Note: COMPLEX parameters are not needed if matched UNLOAD and CKFREEZE files are used.

Example - allocations for internal merge

To merge with rename inside a system SYS1 specify the following commands.

```
ALLOC TYPE=UNLOAD   DSN=my.SYS1.UNLOAD
ALLOC TYPE=CKFREEZE DSN=my.SYS1.CKFREEZE
ALLOC TYPE=CKRCMD   DSN=my.SYS1.CKRCMD
ALLOC TYPE=UNLOAD   DSN=my.SYS1.UNLOAD  FUNCTION=MERGE
ALLOC TYPE=CKRCMD   DSN=my.SYS1.CKRCMD2 FUNCTION=MERGE
```

Note: COMPLEX parameters are not needed if matched UNLOAD and CKFREEZE files are used.

Example - allocating a <deftype> file

```
DEFTYPE TYPE=EMAIL
ALLOC TYPE=EMAIL DSN=HR.PERSONEL.EMAIL
```

BDAMQSAM

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•	•	•	•	•		

This command can be used to deactivate EXCP I/O to the RACF database and use BDAM and QSAM access methods instead. Under VM, this is the only supported mode of operation. The main purpose of this command is to debug problems. Specifying this command also deactivates fast access through the index. However, if that is the only reason for using the BDAMQSAM command, it is better to use the SUPPRESS INDEX command.

BUNDLE

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

This command can be used to group the output of multiple NEWLIST commands together such that all output is generated per distinct value of the BUNDLEBY parameter. For example, the BUNDLEBY parameter allows you to bundle relevant information per department. The NEWLIST group is terminated by an ENDBUNDLE command. The BUNDLE...ENDBUNDLE group can include MERGELIST....ENDMERGE groups. The merged result is treated as a single NEWLIST. The output for each bundle begins on a new page unless it is emailed. If the email option is selected, separate emails are sent for each bundle. If the PAGERESET option is specified (on OPTION, BUNDLE, or the first NEWLIST within the BUNDLE) each bundle restarts its page numbering at 1. Within each bundle, the NEWLISTs display in the order specified. The resulting reports contain the actual BUNDLEBY value in the title, behind the NEWLIST source time stamp. NEWLISTs of different types can be combined into one bundle. BUNDLE commands cannot be nested.

The LIST, DISPLAY, and DSUMMARY commands are not permitted within a bundle. Only commands that generate output and permitted are SORTLIST and SUMMARY. SUMMARY requests for a NEWLIST are applied to the set of records for each BUNDLEBY value separately. For example, if you are generating output per department, each department gets its own summaries.

The BUNDLE command is closely related to NEWLIST and OPTION, in the sense that OPTION parameters can also be included on the BUNDLE command. See "OPTION" on page 856. The OPTION parameters specified on the BUNDLE are local to the BUNDLE...ENDBUNDLE group. They are the default for each NEWLIST in the group, while each NEWLIST can specify overriding parameters that apply to that NEWLIST only. The MAILTO= option is not supported for a bundle. Use the BUNDLEMAILTO= instead. Mail options apply to the bundled output, not the individual NEWLISTs; therefore, they cannot be specified on commands between BUNDLE and ENDBUNDLE.

BUNDLEBY= *variablename*
Request the output to be bundled per distinct value of the specified *variablename*. This *variablename* can either be a field name or a name used with the DEFINE...AS command. The BUNDLEBY option can also be specified on the OPTION command (defining a default) or on a NEWLIST command. If it is specified on a NEWLIST command, it applies only to that NEWLIST type.

The *variablename* can evaluate to a different variable per NEWLIST type. The most effective bundling method is to issue global DEFINEs with the same variable name for each NEWLIST type, and then specify that variable name in the BUNDLEBY parameter for the BUNDLE statement.The values of the BUNDLEBY variable are bundled by their internal representation. The bundle sort order is the same as for SORTLIST. A BUNDLEBY specification is ignored outside a BUNDLE.

BUNDLEMAILTO= *expression*
BMT=*expression*
Request the bundled output to be emailed to the group responsible for each part of the report. This parameter can only be specified on the BUNDLE command. The expression must be a set of field manipulation functions, see "Field value manipulation" on page 760 based on the BUNDLEBY variable. The resolved string is interpreted as an address list conforming to RFC (2)822, with some restrictions. The restrictions are documented with option MAILTO, see 860. If the expression does not resolve, the email address specified on the ERRORMAILTO parameter is used. See "ERRORMAILTO" on page 859. The subject of the resulting emails is based on the title or toptitle specified on the first nonempty NEWLIST in the BUNDLE, with the BUNDLEBY value appended.

Note: When using any of the MAILTO commands, be sure to specify correct SMTPWRITER and SMTPCLASS options, or include a C2REMAIL DD-statement with an allocation to the SMTP writer, see "C2REMAIL" on page 702. Additionally, be sure to include at least one sender address on either the FROM, REPLYTO, SMTPMAILFROM, or ERRORMAILTO keyword. Also be aware that the email function of Security zSecure is not intended to be used in combination with the INFOPRINT email support as introduced in z/OS V1R5.

Example - emailing bundled output to departmental managers

In this example, the site stores department contact information in a file with records containing the names of the departments and the email addresses of the

responsible managers, separated by a colon. The following code sample, shows the CARLa statements for distributing zSecure reports using this departmental contact list.

```
DEFTYPE TYPE=email
DEFINE TYPE=email dept AS WORD(RECORD,1,':')
DEFINE TYPE=email address AS WORD(RECORD,2,':')
ALLOC TYPE=email DSN=my.email.address.file
//*Insert appropriate DEFINEs for owner in each
//* NEWLIST type used in the BUNDLE where it is not a field
//* or you want to change the to override the default meanin//* g.
 //* Insert the required BUNDLEBY statement.BUNDLE BUNDLEBY=owner
BUNDLEMAILTO=BUNDLEBY:email.dept.address

<>
//* Insert the NEWLIST blocks that specify the reports for bundling.
ENDBUNDLE
```

This specification bundles the output per value of **owner**, and then for each bundle look for the record in **my.email.address.file** that starts with this value, and then take the email address specified for it after the colon and send the bundle there.

The OWNER field is not required on the SORTLIST/SUMMARY statement. That is, you can use a field or variable for bundling without including it in the reports.

Example - bundling NEWLISTs

This example shows how to bundle reports by department on a site where the RACF database is organized in the following way. Each RACF group that follows the SYSUSER group defines a department. Each department group contains among others a user-owning group that owns all user IDs of the department. In addition, the department group contains authorization groups giving access to the departmental applications. The departmental report covers both RACF data and SMF data (available in zSecure Audit for ACF2 only), and bundles three reports: data on the department (RACF), data on invalid password attempts on user IDs of the department, and connects to the departmental authorization groups.

```
  /* define default bundle selector */
define type=racf department(8) as key,
       where class=group owner=sysuser
define type=smf department(8) as user:owner:owner,
       where user:owner:owner:owner=sysuser

  /* a bundle for each department */

bundle bundleby=department f=ckreport,
       tt='Departmental report'

n type=racf name=XXXstart t="Information on department",
  pagereset, pagealign=4
  s class=group owner=sysuser
  sortlist key(8,"Department") instdata("Data from RACF"),
         / "user:   " userid userid:pgmrname,
         / "subgrp: " subgrpnm subgrpnm:instdata,
         /

n type=smf name=XXXlogpw t="Invalid password attempts"
  s type=80 event=racinit(1) exists(department)
  sortlist user,
           user:pgmrname("Info from RACF"),
           date time,
           '  /*' recorddesc

n type=smf name=XXXautha t="Authorisation add"
  define department(8) as racfcmd_group:owner,
         where racfcmd_group:owner:owner=sysuser
  s type=80 event=connect exists(department)
  sortlist racfcmd_group("AuthGroup",9),
           racfcmd_group:instdata("Info from RACF"),
           user("Administrator",13),
           racfcmd_user("User"),
           racfcmd_user:pgmrname("Info from RACF"),
           date time,
           '  /*' racfcmd(wrap,hor,0)

endbundle
```

CAPS

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

Use the CAPS command without parameters to force all subsequent SYSPRINT output to uppercase. This command is useful if your print chain does not print lowercase characters. The output containing a listing of the input commands up to and including the line containing the CAPS parameter is not converted to uppercase.

To print reports in uppercase, use the OPTION CAPS command, see “PRINT” on page 870.

Limitation: DBCS characters in the output for a NEWLIST statement are not affected by the CAPS option if the corresponding NEWLIST statement also has a DBCS option. In all other cases, including a listing of the input commands, DBCS characters are not preserved.

CONVERSION

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

The primary usage of conversion rules or conversions is to consolidate similar data during Access Monitor data set consolidation. The CONVERSION command is used to define conversion rules that can replace name segment qualifiers of SUMMARY key fields with fixed characters, if the Access Monitor record matches a selection criterion. Conversion rules have global scope and they are identified by name and NEWLIST type. Conversion rules can be used only in commands that follow the CONVERSION command in the query.

The CONVERSION command (abbreviated as CONV) has the following basic syntax.

```
CONVERSION
   [ TYPE=type ]
   name
   actions
   [ WHERE clause ]
```

TYPE
The TYPE=*type* parameter is optional. It defines to which NEWLIST type the conversion applies. The default type is the ACCESS NEWLIST. The RACF NEWLIST is not supported.

name
The conversion identifier. The TYPE=*type* and *name* form an identification key for the conversion.

actions
The list of actions to be performed on the summary key value. This list has the following syntax:

```
REPLCHAR((subfield,char)[,(subfield,char),...])
```

The *subfield* identifies a qualifier in a SUMMARY key field and can be one of the following identifiers.

Identifier	Description
QUAL*n*	Refers to qualifier *n* of the summary key; *n* is a number from 1 to 123. If the field value is aaa.bbb.ccc, then QUAL1 is aaa, QUAL2 is bbb, and so on.
LASTQUAL	Refers to the last summary key qualifier. If the field value is aaa.bbb.ccc, the LASTQUAL is ccc.
SUBSTRING	Refers to a part of a subfield: QUAL*n* or LASTQUAL. The SUBSTRING has the following syntax: `SUBSTRING(QUALn | LASTQUAL , startpos, length)` The *startpos* is the start position of the substring of the subfield. You can express the length using a *length* or *endpos* variable. For format details, see "SUBSTRING, SUBSTR" on page 763 in "Field value manipulation" on page 760. The command abbreviation is SUBSTR.

WHERE

The optional WHERE clause is an expression that is formed like a SELECT clause for the NEWLIST type=*type* and uses the same fields, relationship operators, and so on. The WHERE clause is evaluated before the conversion is applied. If the evaluation result is TRUE, the conversion is applied; otherwise, it is skipped. Additional field manipulation functions are defined for this clause in the CONVERSION context, see QUALIF, QUALNUM, LASTQUAL, and PICT in "Field value manipulation" on page 760.

The examples at the end of this section show the use of a WHERE clause for the CONVERSION command.

Examples of CONVERSION command syntax

Example 1

```
CONVERSION conv1 REPLCHAR((qual1,'a'))
```

Defines a conversion named conv1 of default type ACCESS NEWLIST that replaces the characters of the first qualifier with the character a. For a field value of xxx.yyy.zzz, conv1 changes it to aaa.yyy.zzz.

Example 2

```
CONVERSION TYPE=ACCESS conv2 REPLCHAR((qual1,'a'),(qual2,'b'))
  WHERE (class=dataset,qual(resource,1)='C2PACMON',qualnum(resource)=5)
```

Defines a conversion named conv2 of explicit type ACCESS NEWLIST that replaces the first qualifier in the field value by characters a and the second qualifier in the field value by characters b.

This conversion is completed for records where the value of the CLASS field is DATASET, the first qualifier of the RESOURCE field value is C2PACMON, and the number of qualifiers for the RESOURCE field is 5. For example, if the field value is c2pacmon.www.xxx.yyy.zzz, conv2 changes it to aaa.bbb.xxx.yyy.zzz.

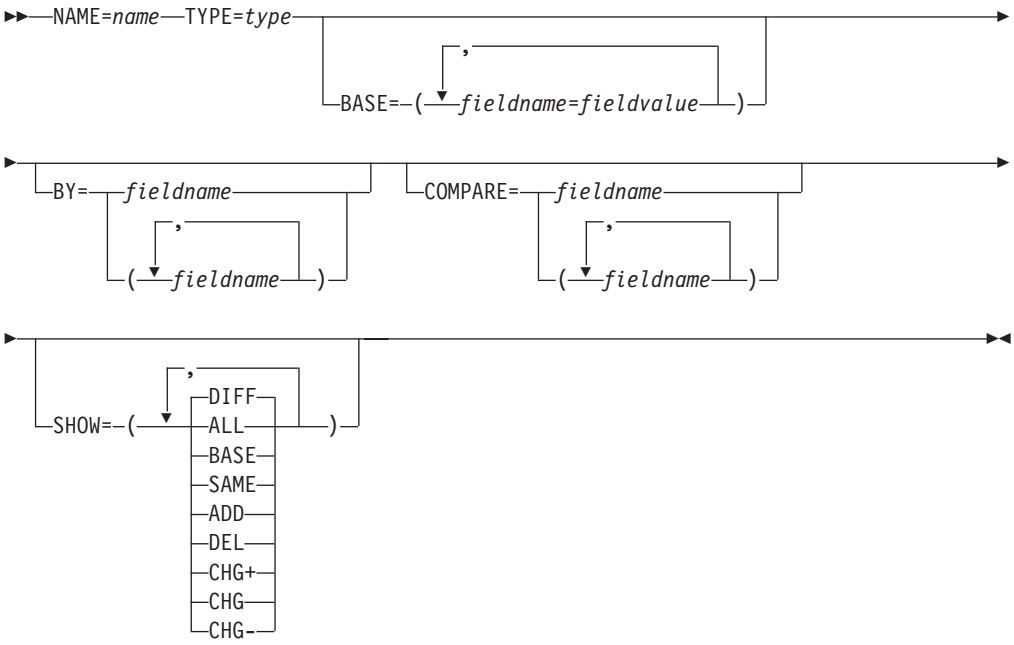
COMPAREOPT

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

The COMPAREOPT statement defines a set of comparison properties to be used by any NEWLIST that references it using the COMPAREOPT=name option. The COMPAREOPT statement specifies what is to be compared in a comparison process and what is to be shown in the output. For information about how compare processing works, see "Compare processing" on page 46.

The COMPAREOPT has the following syntax:

CompareOpt



The parameters available for the COMPAREOPT statement are described in the following sections.

NAME=

Specifies the name of this COMPAREOPT statement. The name is used to select this COMPAREOPT specification in a NEWLIST statement. This field is required. The name *DEFAULT* is a pre-defined compare specification that cannot be modified. It is established by the ALLOC FUNCTION=BASE option. See "ALLOCATE" on page 718.

The NAME parameter must be specified before the BASE parameter option.

TYPE=

This required field specifies the NEWLIST type to which this COMPAREOPT statement applies.

The TYPE parameter must be specified before the BY, BASE, and COMPARE parameters.

BASE=

Specifies the criteria to be used to locate the record that reflects the BASELINE. It is specified in the form of a SELECT clause appropriate for the NEWLIST type. If no base is specified, the lowest value present in the record collection is used. For more information, see "Compare processing" on page 46.

The value for the BASE parameter can also be set using the `ALLOC FUNCTION=BASE` specification. For details, see the FUNCTION parameter in "Explicit allocation mode" on page 720.

BY=

Specifies the key of the record to be used in the comparison process. No DEFINE variable names are supported here. Do not include any fields used in the BASE specification. If it does, each set of BY values contains only one record with a compare result value of either ADD or DEL. Many NEWLIST fields have a default set of BY variables. You can use `TYPE=FIELD` to obtain this default set.

COMPARE=

Specifies the fields to be used in the comparison process. No DEFINEd variables are supported here. Not all variables are supported. You can use `TYPE=FIELD` to determine which fields are supported.

SHOW=

Specifies the records to be included in the resulting display or report. A value of *ALL* is equivalent to all possible values. A value of *DIFF* represents a composite of `ADD`, `DEL`, `CHG`, `CHG+`, and `CHG-`. For an explanation of these values and other possible values, see "Defining variables for comparison results (COMPAREOPT)" on page 754.

Processing considerations

- If any of the BASE, BY, or COMPARE field names specifies the name of an unsupported field, an error message is issued. Then, after the parsing phase, the program stops. To prevent this problem, you often need to use the default values, or to list all the comparison fields that you are interested explicitly.
- For the BY= parameter, unsupported fields mainly include structured repeated fields.
- For the COMPARE= specification, unsupported fields include those fields that cannot reasonably be compared and represented in a report. Examples are repeated combination fields, like ACL and CONNECTS. Simple repeated fields are supported, although most of these do not provide useful information when used out-of-context, USERACS for example.
- You cannot specify lookup fields or defined variables for any of the BY or COMPARE field names.
- Although you can specify a field as both a compare field (COMPARE) and a record key (BY) field, this specification is not useful. The compare process result for this specification is *fields are equal*. Almost the inverse applies to specifying the same field as a compare field (COMPARE) and as part of the baseline key (BASE). In that case the outcome of the comparison process is BASE (for the baseline record) or one of the difference values for all other records.

COPY

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
		•	•			

The COPY command generates RACF commands to copy the user or group profile including all attributes and all segment information that can be set by RACF commands. The connects are also copied, including all connect attributes except the connect OWNER, which is always set to the group. When you copy user- or group-specific profiles, all occurrences of the user or group are replaced by the target ID. User- or group-specific profiles are profiles with the user or group at a predefined qualifier in the profile key. If you supply a CKFREEZE file, IDCAMS commands are used to copy the corresponding catalog aliases.

Note: The REMOVE command is only supported if you have IBM Security zSecure Admin installed and enabled.

The COPY command does not issue any commands by itself. The generated RACF commands are written to the CKRCMD file. The commands in this file can also be generated as the result of the following commands: MOVE, REMOVE, VERIFY command or a PRINT DD=CKRCMD statement. If commands are being queued from the interface, then commands in CKRCMD can also be generated by overtyping, including the extra SETROPTS REFRESH commands. To complete the copy operations, verify and confirm the commands in the CKRCMD file, and then run them.

The COPY command generates the RACF commands for each complex/security database that has the model user defined. When the commands are run from the CKRCMD file, the operations can fail if the requisite profiles have disappeared. For example, if an existing profile to be copied refers to another profile that has been deleted, the copy operation fails. The failure occurs because RACF only checks validity at the time a profile is being added or modified and does not enforce referential integrity.

Some information cannot be copied by regular RACF commands. Most notably, these include a user's initial TSO command and the TSO User Profile Table, which are both options set by the TSO PROFILE command.

The COPY command syntax is similar to the syntax for the COPY and REMOVE commands. The COPY command is mutually exclusive with VERIFY PERMIT and VERIFY STC commands.

The keys and members of RACFVARS profiles are by default interpreted as users and groups when they match a valid user or group id, and they are managed accordingly, unless you specify the SUPPRESS MANAGERACFVARS command for the run. A discrete first qualifier in the key of a STARTED profile is only interpreted as a user ID when it matches the specification in the STUSER field in the STDATA segment.

You can specify the information to be copied using the COPY parameters described in “COPY parameter descriptions” on page 742. “Using the COPY command” on page 746 provides examples of using the COPY command and parameters.

When the COPY command runs, the resulting messages are similar to the messages generated by the MOVE and REMOVE commands except the COPY messages include *Copy* or *Replace* terms instead of *Delete* and *Remove*. The term *Replace* is used when a command has been generated to remove a permit to the original user/group in a new profile. It is also used when a command has been generated to replace a field in a new profile (OWNER, for example). The term *Copy* is used if a new permit has been added as a copy of a permit to the original user/group. The COPY messages can also include the phrase *Resource copying:* when referencing new catalog aliases.

COPY parameter descriptions

Use the following parameters to specify the user or group information to copy and the target and where it is to be copied. The order in which the parameters are specified is significant. For examples showing how to use the COPY command, see "Using the COPY command" on page 746.

PERMIT= *id* **TOUSER=***id2*
Generate commands that would add permits for user *id2* to all access lists containing permits for user or group *id*. In addition copies of all generic data set profiles starting with the user or group id are added. The scope of the command can be limited by using the SELECT QUAL= command.

PERMIT= *id* **TOGROUP=***id2*
Generate commands that would add permits for group *id2* to all access lists containing permits for user or group *id*. In addition copies of all generic data set profiles starting with the user or group *id* are added. The scope of the command can be limited by using the SELECT QUAL= command.

PERMIT= *id* **TOPERMIT=***id2*
Generate commands that would add permits for user or group *id2* to all access lists containing permits for user or group *id*. In addition copies of all generic data set profiles starting with the user or group *id* are added. The scope of the command can be limited by using the SELECT QUAL= command.

USER= *id* **TOUSER=***id2*
Generate commands to copy a user including its usrdata, segments, connects, permits, and the profiles used by that user only. This parameter does all processing of COPY PERMIT, and also generates RACF commands to create the user to its default group, connects it to the other groups, creates copies of all generic data set profiles starting with user ID, and creates copies of all general resource profiles or members with the user ID in functional positions in profile keys of the following classes:

- DATASET
- DLFCLASS
- INFOMAN
- JES: JESJOBS, JESSPOOL
- CICS: TCICSTRN, GCICSTRN, DCICSDCT, ECICSDCT, FCICSFCT, HCICSFCT, ACICSPCT, BCICSPCT, JCICJCT, KCICSJCT, MCICSPPT, NCICSPPT, PCICSPSB, QCICSPSB, SCICSTST, UCICSTST, CCICSCMD, VCICSCMD
- VM: VMMDISK, VMRDR, VMBATCH, VMCONECT, VMEVENT, VMXEVENT, VMCMD
- LFSCLASS
- SURROGAT
- PROPCNTL
- PTKTDATA

When copying a profile, permits and the OWNER and NOTIFY fields are also replaced if they contain the user ID to be replaced in the original profile. The scope of the command can be limited by using the SELECT QUAL= command as well as by the SUPPRESS ADDSD command. The connects to be defined can be regulated by the FROMGROUP and TOGROUP parameters. If FROMGROUP specifies a list of groups, the new user ID is not connected to any of these groups. If TOGROUP is specified, a connect with default attributes is added for that group. More than one COPY USER=*id* can be present for the same id to create a

set of user IDs with identical setup. COPY for an already defined user does not generate the CONNECT and ALTUSER commands by default. This prevents a user from inadvertently copying over an existing user ID. You can make a conscious decision to copy to a user ID that exists: by suppressing messages 535 and 536 (option **SE.0**), the commands will be generated even though the user exists.

GROUP= *id* **TOGROUP=***id2*
Generates commands to copy a group, including its segments, connects, permits, and the profiles solely used for that group. This parameter does all COPY PERMIT= processing and in addition it generates the RACF commands to add the group below the same superior group, create connects to the same users, create copies of all generic data set profiles starting with group, and create copies of all general resource profiles with the group in functional positions in profile keys of the following classes:

- DATASET
- DLFCLASS
- VM: VMMDISK, VMRDR, VMBATCH, VMCONECT, VMEVENT, VMXEVENT, VMCMD
- SURROGAT
- PROPCNTL
- PTKTDATA
- LFSCLASS
- JES: JESJOBS and JESSPOOL

When copying a profile, permits and OWNER fields are also replaced if they contain the group to be replaced in the original profile.

The following options can be used to modify the processing of the COPY USER=*id* TOUSER=*id2* command.

NEWDCEUUID('*new uuid***')**
NEWDCEUUID='*new uuid***'**
This parameter can be used with COPY USER=*id* TOUSER=*id2* command to set the DCE UUID for the new user ID. The string can be enclosed in single, double, or left quotation marks.

NEWDATA('*new installation data***')**
NEWDATA='*new installation data***'**
This parameter can be used with the COPY USER= TOUSER= command or COPY GROUP= TOGROUP= commands to set the installation data on the new ID. The string must be enclosed in single, double, or left quotations.

NEWDFLTGRP(*group***)**
NEWDFLTGRP=*group*
This parameter can be used with COPY USER= TOUSER= command to set the default group on the new user ID. It implies TOGROUP=group which means that a new default connect will be added if the original user ID was not connected to this group.

NEWKERBNAME('*new kerbname***')**
NEWKERBNAME='*new kerbname***'**
Use this parameter with the COPY USER= TOUSER= command to set the Kerberos principal name for the new user ID. The string can be enclosed in single, double, or left quotes. The Kerberos principal name is case sensitive and can contain internal blanks. You must specify a unique value for each user.

NEWNAME(*newname***)**
NEWNAME=*newname*
This parameter can be used with `COPY USER= TOUSER=` command to set the name on the new user ID. The string can be enclosed in single, double, or left quotation marks.

NEWOMVSGID(*new gid***)**
NEWOMVSGID=*new gid*
This parameter can be used with the `COPY USER= TOGROUP=` command to set the OMVS GID for the new group. The value of the new gid can be one of the following:

- A number (for example: 1234). The number that you specify is assigned as the gid for the new group.
- A number followed by the letter S (for example: 1234S). The value that you specify is assigned as the gid for the new group, using the SHARED keyword.(available in z/OS 1.4 or with APAR OW52135).
- The word AUTO. This value automatically assigns the new group a unique gid by using the AUTOGID command(available in z/OS 1.4 or with APAR OW52135).

If the NEWOMVSGID keyword is not present on the copy command, the value of the gid for the source group is used, and if running on z/OS 1.4 or later, the SHARED keyword is added.

NEWOMVSHOME('*new home directory***')**
NEWOMVSHOME='*new home directory***'**
This parameter can be used with `COPY USER= TOUSER=` command to set the OMVS path for the home directory for the new user ID. The string can be enclosed in single, double, or left quotation marks. The HOME path name can consist of any characters, including quotations.

NEWOMVSPROGRAM('*new shell command***')**
NEWOMVSPROGRAM='*new shell command***'**
This parameter can be used with `COPY USER= TOUSER=` command to set the OMVS path for the shell command for the new user ID. The string can be enclosed in single, double, or left quotation marks. The PROGRAM path name can consist of any characters, including quotations.

NEWOMVSUID(*new uid* **)**
NEWOMVSUID=*new uid*
This parameter can be used with `COPY USER= TOUSER=` command to set the OMVS UID for the new user ID. The value of *new uid* can be one of the following:

- A number (for example: 1234). The number that you specify is assigned as the uid for the new user.
- A number followed by the letter S (for example: 1234S). The value that you specify is assigned as the gid for the new group, using the SHARED keyword. (available in z/OS 1.4 or with APAR OW52135).
- The word AUTO. This value automatically assigns the new group a unique gid by using the AUTOGID command(available in z/OS 1.4 or with APAR OW52135).

If the NEWOMVSUID keyword is not present on the copy command, the value of the source users uid is used, and if running on z/OS 1.4 or higher, the SHARED keyword is added.

NEWOWNER(*owner***)**
NEWOWNER=*owner*
This parameter can be used with `COPY USER= TOUSER=` command to set the owner on the new user ID.

NEWPHRASE('*phrase***')**
NEWPHRASE= '*phrase***'**
Use the NEWPHRASE parameter to set the password phrase on the new user ID. The password phrase value is case-sensitive. When you specify the value, it is not echoed in the SYSPRINT. The following syntax rules apply to the value specified for phrase:

- Maximum length: 100 characters.
- Minimum length: nine characters if ICHPWX11 is present and 14 characters if ICHPWX11 is not present.
- Must not contain the user ID (as sequential uppercase or sequential lowercase characters).
- Must contain at least two alphabetic characters (A–Z, a–z).
- Must contain at least two non-alphabetic characters (numerics, punctuation, or special characters).
- Must not contain more than two consecutive characters that are identical.
- If a single quotation mark is intended to be part of the password phrase, you must use two single quotation marks together for each single quotation mark.

The NEWPHRASE parameter is mutually exclusive with the PROTECTED parameter.

NEWPASSWORD(*password***)**
This parameter can be used with `COPY USER= TOUSER=` command to set the password on the new user ID. The password is not echoed on SYSPRINT. It is mutually exclusive with the PROTECTED parameter.

NEWSNAME('*new sname***')**
NEWSNAME='*new sname***'**
This parameter can be used with `COPY USER= TOUSER=` command to set the Lotus Notes short name for the new user ID. The string can be enclosed in single, double, or left quotation marks. The `sname` is case sensitive and can contain internal blanks. You must specify a unique value for each user.

NEWUNAME('*new uname***')**
NEWUNAME='*new uname***'**
This parameter can be used with `COPY USER= TOUSER=` command to set the NDS user name for the new user ID. The string can be enclosed in single, double, or left quotation marks. The `uname` is case sensitive and can contain internal blanks. Make sure that this field has a unique value for each user.

FROMGROUP(*idlist***)**
FROMGROUP=*id*
FROMGROUP=(*idlist***)**
This option causes a user ID not to be connected to the groups specified in *idlist*, which can be a single group name, or a list of group names enclosed in parentheses and separated by commas. Multiple FROMGROUP parameters have the same effect as a list of groups. If a group happens to be the default group of a user, the default group is changed to one of the TOGROUP groups (if present, which one exactly is unpredictable), or another connect.

TOGROUP= *idlist*[5]
This option can be added to the `COPY USER=` command to indicate additional connects to be created. They are specified as *idlist*, which can be a single group name, or a list of group names enclosed in parentheses and separated by commas. Multiple TOGROUP parameters have the same effect as a list of groups. In addition, it can be used as an alternative default group if a FROMGROUP happens to be the default group of a user.

PROTECTED
This parameter can be used with `COPY USER= TOUSER=` command to protect the password on the new user ID. This means that the user ID has no password and cannot be used in logon procedures.

The PROTECTED parameter is mutually exclusive with the NEWPASSWORD and NEWPASSPHRASE parameters.

REVOKE
This option can be used on the `COPY USER=` command to revoke the user ID as well as performing the other actions on the COPY command.

Note: All parameters except NEWPASSWORD and NEWPHRASE can also be specified as `parm(value)` in addition to `parm=value`.

Using the COPY command

The following examples show the command syntax to use for various copy tasks such as copying a user or a group.

Copying permits

The following example generates commands to copy permits. The COPY PERMIT command adds a user SMITH on all access lists that contain user JONES, with the same access permitted as for user JONES, and creates generic data set profiles starting with SMITH for ones starting with JONES, to allow the same access to corresponding data sets.

```
copy permit=jones touser=smith
```

Copying permits selectively

The following example generates commands to copy permits for a specific user ID JONES to another user SMITH, and creates generic data sets profiles starting with SMITH for the ones starting with JONES, but only for profiles with MYAPP as their first qualifier.

5. Idlist is one or more ids separated by commas or blanks.

```
select qual=myapp
copy permit=jones touser=smith
```

Copy user

The following example generates commands to create a clone of user JONES, and call it SMITH.

```
copy user=jones touser=smith newname='JOHN SMITH'
```

If you omit the new name, the name is copied from JONES.

For details on controlling password-related information for the new user ID, see "COPY parameter descriptions" on page 742 the NEWPASSWORD, NEWPHRASE, and PROTECT parameter descriptions.

Copying user - leave revoked

The following example generates commands to clone a user ID JONES and call the clone SMITH, but revoke the new SMITH user ID.

```
copy user=jones touser=smith revoke
```

Copying a group

Generates commands to copy permits, connects, and group-specific profiles for a group OLDGRP to another group NEWGRP.

```
copy group=oldgrp togroup=newgrp
```

Copying a user without resource profiles

The following command example generates the commands to copy permits, connects, and user attributes for a user ID JONES to another user SMITH without copying the user-specific profiles.

```
copy user=jones touser=smith
suppress addsd
```

Copying a user to another group

```
copy user=jones touser=smith
fromgroup=oldgrp togroup=othergrp
```

The following example generates the commands to copy the permits, connects, user attributes, and user-specific profiles for the user ID JONES to the SMITH user ID and connects SMITH to a new group (OTHERGROUP) instead of the group that JONES was connected to (OLDGROUP).

In this case, the connect attributes of `SMITH/OTHERGRP` are the default, `AUTH(USE)`, instead of any attributes of `JONES/OLDGRP`.

Copying a user without catalog aliases

The preceding examples clone catalog aliases for which the sourceid is the HLQ. This example clones a user but does not create any catalog aliases.

```
copy user=jones touser=smith newname='JOHN SMITH'
suppress copyalias
```

Cloning multiple user IDs from a model user

The following example generates a set of user IDs from one model.

Important: Do not use a fixed algorithm for deriving new passwords.

```
copy user(coursem) touser(course1) newname('student 1'),
newpassword(student1)
```

```
copy user(coursem) touser(course2) newname('student 2'),
newpassword(ticpw2)

copy user(coursem) touser(course3) newname('student 3'),
newpassword(yapfstu3)

copy user(coursem) touser(course4) newname('student 4'),
newpassword(newpwst4)
```

DEBUG

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

This command is meant to diagnose problems in the operation of the program. With the exception of the following parameters, most of the DEBUG parameters are not documented in this manual. Use the DEBUG command when advised to do so by IBM Software Support.

This command is not supported in restricted mode, except for PERFORM, DICT, ACTION, CPIC, RESTRICT.

The DEBUG options that are documented are:

ABEND
Issues an immediate user abend 16 for the purpose of testing error recovery procedures and stops further processing.

ACTION
Prints the message CKR2829 to list the National Language Support decisions during processing of an action command under ISPF. This field also prints CKR2670 messages to document the substitution map being used by a FORALL command.

CPIC
This parameter no longer has meaning since CPI-C support has been removed from the program.

EMAIL
This option can be used to diagnose email address problems. It lists messages detailing the program's understanding of the email address passed in terms of phrase, local-part, and domain. It also lists the line length used for the email output.

FIELD
Gives detailed diagnostic information about the processing of fields from RACF profiles.

GUARD
Branches to an odd address (0C6 abend) within guarded code. This should not lead to a crash.

INDEX
This parameter requests debug output that lists which profiles are actually read from a RACF data set, and which profiles lookups are taking place. It can be used to debug query response time problems. This parameter is not supported in restricted mode.

LICENSE

This causes install, entitlement, and product enablement status to be listed in the SYSPRINT.

DEBUG LICENSE only has effect if it comes in the input before any CARLa constructs that need access to entitlement information for some reason (like a DEFINE before the first NEWLIST). Generally this means it is most effective when passed in the parameter string. For the ISPF interface, you can use the Preamble, see "SE.3 Setup - Preamble" on page 1654.

PERFORM
This parameter does the following:

- Requests debug output that details which NEWLIST / select can exploit the RACF data set index.
- Lists the initial key request queue.
- Can be used to debug query response time problems.
- Triggers the creation of CKR1698 messages in the `SYSPRINT`.

  These messages report elapsed and CPU time at various stages in the processing. They report both the delta since the previous CKR1698 (or start of program for the first message), and the total elapsed time since the program started. Information is more complete under ISPF, providing the status messages themselves in the `SYSPRINT` with record counts and other information. In batch mode, only the ISPF message number is listed without the message content.

This parameter is supported in restricted mode.

READALL
This parameter requests debug output concerning the tests for the CKR.READALL profile in the CKRSITE class.

RESTRICT
Prints message CKR2854 to list the TCB dirty bits and the module dirty bits of all modules in the Job Pack Queue to help in PADS debugging. This is also automatically activated by a 913 abend on CKFREEZE, CKRUNLIN, or a RACF database.

SEGMENT
This parameter requests debug output that shows where a user or group segment was found that could not be accurately assigned to the proper entity type. This may happen for OMVS segments that have only the field UID filled in.

SVC99
This debug option shows all debugging information for all SVC 99 (DYNALLOC) calls being done.

DEFAULT

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

This command can be used to change defaults. They apply for the complete run.

OWNER= *id*
Select a different default ownership than SYS1 for non-data set profiles that have an undefined owner or an owner that is to be removed.

SYSTEM= *id*
SYST=*id*
SYS=*id*
Select system to use as viewpoint if only one system at a time is supported. This applies for instance to the REPORT AC1 command. complex simply is the one the default system has been assigned to. The default system and complex are listed in the SYSPRINT file in the CKR0615 message.

If the DEFAULT specification is omitted, an arbitrary system is selected from any CKFREEZEs present. However, if one of the CKFREEZE files applies to the current system, then this is used as the default system (if the DEFAULT specification was omitted).

DEFINE

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

The DEFINE command is used to define variables for several purposes.

- *Statistic variables* to be used with the (D)SUMMARY command.
- *Boolean variables* for use with the (D)SUMMARY, SORTLIST, LIST and DISPLAY commands, and non-RACF SELECT and EXCLUDE commands. There are two kinds of Boolean variables, BOOLEAN and TRUE; the type BOOLEAN is a summary statistic and cannot be part of a summary key, the type TRUE is a field and can be part of a summary key. The difference is only apparent on the (D)SUMMARY command.
- *Subselect variables* to list selected repeat group instances with the SORTLIST, LIST, and DISPLAY commands.
- *Field-based variables* to define a variable based on a field, but with a different layout or with conditions attached, for use with the (D)SUMMARY, SORTLIST, LIST and DISPLAY commands, and non-RACF SELECT and EXCLUDE commands.

If a variable is defined that has the same name as a built-in field, the defined variable is used in the SELECT and EXCLUDE output commands. Within a DEFINE command, the field on which a variable is defined is always the original field. The DEFINE command can be abbreviated to DEF.

Variables defined with a DEFINE command apply to one NEWLIST type unless TYPE=* is specified. TYPE=* is a multi-type define that results in the variables being defined being available in all NEWLIST types. Variables can have local scope (that is, become undefined at the next NEWLIST) or have global scope (that is, remain defined until overridden). To indicate the NEWLIST type to which the variable applies, the TYPE= parameter is used. If not used, the current NEWLIST type is used by default. (Before the first NEWLIST, type=RACF is implied.) The following table shows how the scope of a DEFINE is set:

Table 287. DEFINE Scope

Within a NEWLIST	Using TYPE=	Type	Scope
Yes	Yes	*	Global, Multi-type
No	No	RACF	Global
No	Yes	from TYPE	Global

Table 287. DEFINE Scope (continued)

Within a NEWLIST	Using TYPE=	Type	Scope
Yes	No	from NEWLIST	Local, unless first definition
Yes	Yes	from TYPE	Local, unless first definition

Variables that are defined can only be used in commands that are situated *after* the DEFINE and are within scope of the define. Since the first definition of a variable with a certain name and type always has a global scope, this means that the variable can be used in all commands beyond the DEFINE. When both a global and a local variable with the same name and type are in scope for a NEWLIST be aware that the local variable is used in all commands following the local DEFINE and the global variable is used in all commands preceding it.

The DEFINE command has the following basic syntax:

```
DEFINE
    [ TYPE=type ]
    [ HELPPANEL=panelname ]
    varname[(modifiers)]
    definition
    [ WHERE clause ]
```

The general *definition* syntax is

```
kind[specification]
```

TYPE

The TYPE=*type* parameter is optional. It defines to which NEWLIST type the definition applies. The default is that the definition applies to the current NEWLIST type (if in the scope of a NEWLIST), or RACF if the DEFINE is not in a NEWLIST scope.

To define a variable, `varname` for all NEWLIST types, use `TYPE=*`. Specifying `TYPE=*` can reduce some of the maintenance effort for defining statistical fields that are often used in multiple newlists. The use of TYPE=* is also called a *multi-type define* in contrast to a *global define* which refers to DEFINE statements specified outside the scope of a NEWLIST.

`TYPE=*` results in the `varname` being available in all NEWLIST types. Using `TYPE=*` can reduce some of the maintenance effort for defining statistical fields that are often used in multiple newlists. The use of `TYPE=*` is also called a multi-type define. The term global define is already in use for defines done outside the scope of a NEWLIST.

If the variable that is being defined exists, one of the definitions needs to be overridden or ignored. For `TYPE=*`, the most recent definition during parse of the CARLa input statements is used. This results in using different definitions for `varname` based on the sequence of define and use statements. The following considerations apply to `TYPE=*`:

- `TYPE=*` is only supported by the following `DEFINE` types: `COMPARE_RESULT`, `COMPARE_CHANGES`, `COUNT`, and `SUMCOUNT`.
- A `WHERE` clause is not supported by `TYPE=*` because select clauses are type-dependent.

HELPPANEL= *panel*

This indicates which help panel to use when field-level help is being requested. This parameter must be specified before the field name on the DEFINE and can be before or after the TYPE= keyword. If this help panel name is not specified,

it defaults to help for the field on which the DEFINE is based. If the specified or default field-specific help panel does not exist, it falls back to the help panel on the NEWLIST or OPTION statement appropriate for the current display level (HELPPANEL, DETAILHELPPANEL, or SUMHELPPANEL). If that is not specified, it defaults to the newlist help panel C2R&CKREREL.xx@0 where xx is the two letter NEWLIST type representation. The panel name specified may contain "&CKREREL." to be replaced with 2 or 3 depending on the ISPF level (2 for VM), but not in the first position.

varname
The *varname* parameter can be 1 to 24 characters long, can contain alphanumeric characters, underscores, and the national characters **#**, **$**, and **@**. The *varname* cannot start with number. National characters cannot be used for output in XML format. To avoid name clashes with predefined fields it is advisable to use two underscores as a prefix.

If a variable is defined that has the same name as a built-in field, the defined variable is used when the name is referred to in SORTLIST and in DISPLAY commands. If you define a variable with the same name as a built-in field, and then use that name as a target for a subsequent define, the built-in field is used, not the defined variable.

The optional modifiers for the DEFINE statement *varname* parameter are described in the following paragraphs:

modifiers
The output modifiers included after the variable are optional. They are described with the LIST command, see “LIST family of commands” on page 794.

kind
This defines the kind of variable. The variable can be AVG, AS, BOOLEAN, COUNT, FREQ, MAX, MIN, SUBSELECT, SUM, SUMCOUNT, or TRUE. The kinds of variables supported are documented in “Defining variables for a summary” on page 753 and “Defining variables for a SORTLIST/DISPLAY” on page 754. See these topics for more information.

specification
The *specification* extends the definition of the *kind* variable. The following syntax shows the supported combinations of *kind specification*:

```
{ {MIN|MAX|AVG|SUM}(field)
  | {COUNT|SUMCOUNT|FREQ|BOOLEAN}
  | {COUNT|SUMCOUNT|FREQ|BOOLEAN}(target variable)
  | {COMPARE_RESULT|COMPARE_CHANGES}
  | SUBSELECT field(subselect clause)
  | AS expression
  | TRUE
}
```

WHERE
The optional WHERE clause is an expression that is formed like a SELECT or EXCLUDE clause for the current NEWLIST type and uses the same fields, relationship operators, and so on. A WHERE clause is not supported for `DEFINE TYPE=*` because SELECT clauses are type-dependent.

If the WHERE clause evaluates to TRUE this means that a similar SELECT clause would have selected the record and the WHERE clause is effective. The effect of the WHERE clause depends on the variable type: a summary statistic is updated, a Boolean is set to ON, or a field-based variable is used.

If the WHERE clause evaluates to FALSE, a statistic is not updated, a Boolean is set to OFF, a subselect is not performed (all instances are skipped), or a field-based variable is missing.

For usage examples, see "Example: WHERE clause for summary statistics" on page 773.

Defining variables for a summary

You can define variables for use in a (D)SUMMARY command to collect statistics about a field, or to count occurrences. Table 288 shows the variable categories that can be defined.

Table 288. Variable categories that can be defined for the SUMMARY command

Kind	Category	Meaning
AVG AVERAGE	field	Average of the fields that are summarized.
BOOLEAN	occurrence	YES if any of the occurrences evaluates to YES, NO otherwise. The only type of variable name that is supported in parentheses behind BOOLEAN is a variable with a WHERE clause. The statistic tests whether the WHERE clause is true in at least one record.
COUNT	occurrence	Count of occurrences. The only type of variable name that is supported in parentheses behind COUNT is a variable with a WHERE clause. The statistic counts the records where the WHERE clause is true.
FREQ FREQUENCY	occurrence	Percentage that the condition clause evaluates to true among occurrences (when combined with a condition clause), or percentage of occurrences selected (without a condition clause).
MAX MAXIMUM	field	Maximum of fields summarized.
MIN MINIMUM	field	Minimum of fields summarized.
SUM	field	Sum of fields summarized.
SUMCOUNT	occurrence	Count of different cases summarized on the next lower level, *after* the lower-level thresholds have been applied. The only type of variable name that is supported in parentheses behind SUMCOUNT is a variable with a WHERE clause. The statistic counts the lower summary levels where the WHERE clause is true in at least one record.

The use of summary statistics and the optional WHERE clause is shown in the examples at the end of this section.

Usage notes

- The NOPROP and *threshold* output modifiers can be used on a (D)SUMMARY command.
- An overriding length also has a special meaning in summaries. See "Modifying output length" on page 797 for more details.
- All variables for SORTLIST and DISPLAY as listed in the next section can be used on the (D)SUMMARY command as well; these act as summary key fields. In particular, TRUE can be used to split records for which the variable is true from those records for which it is false on the summary level, as opposed to BOOLEAN, which merely observes if any value true occurs in the summary category.

Defining variables for a SORTLIST/DISPLAY

You can define variables for use in a SORTLIST/DISPLAY to manipulate the presence, appearance, or contents of (part) of a field.

Table 289. SORTLIST/DISPLAY defined variables

Kind	Category	Meaning
AS	key	Copy of the original field. Useful for BUNDLEBY, to have a set of default overrides (length, format, and so on), to apply field value manipulations, or to only show a field subject to a specific WHERE clause.
SUBSELECT	key	Extract of a repeated field, filtered on the entry level according to a (possibly composite) SUBSELECT clause.
TRUE	key	TRUE, unless its WHERE clause evaluates to false.

Note: You can also use the summary statistic BOOLEAN in SORTLIST or DISPLAY commands. Specifying BOOLEAN is functionally equivalent to TRUE.

More information is available in the topics "Subselect clauses" on page 755, "Field-based defines" on page 760, and "Field value manipulation" on page 760, and in the example topics in this section.

Defining variables for comparison results (COMPAREOPT)

You can define the `COMPARE_RESULT` and `COMPARE_CHANGES` variables to store the results of a comparison process. See "Compare processing" on page 46 for information about the comparison process.

COMPARE_RESULT
Contains the results of the comparison process. Table 290 lists the possible values for the `COMPARE_RESULT` field.

Table 290. COMPARE_RESULT field - possible values

Field	Value
ADD	The baseline record corresponding to the current record is missing.
DEL	The baseline record is present, and the corresponding record in at least one other input source file is absent.
CHG+	Both the current record and the baseline record are present. At least one of the compare fields was found to be different. All changed compare fields support the same level or an increased level of security compliance. At least one of field changes represents an improvement.

Table 290. COMPARE_RESULT field - possible values (continued)

Field	Value
CHG-	Both the current record and the baseline record are present. At least one of the compare fields was found to be different, and at least one of the changed compare fields results in a decreased level of security compliance.
CHG	Both the current record and the baseline record are present. One of the compare fields was found to be different. None of the changed compare fields has an impact on the security compliance level.
SAME	Both the current and the baseline record are present, and all compare fields are identical. This does not necessarily mean that the entire two records are identical. They will differ in the key, and possibly some of the ignore fields.
BASE	The record reflects the baseline record. If the corresponding record in at least one other input source file is absent, the BASE value is suppressed by the DEL value.
MISSING	The current NEWLIST is not the result of a comparison operation. Instead of failing the entire process, the value is missing to reflect that no comparison result is available.

COMPARE_CHANGES

Contains the changes detected during the comparison process. The COMPARE_CHANGES field contains changed fields only. For each field the following values are included: *fieldname*, *compliance direction*, *baseline value*, *changed value*. The COMPARE_CHANGES field is in itself a repeated combination field.

Note: Use the SORTLIST or DISPLAY commands to include the comparison results stored in the COMPARE_CHANGES field in a printed report or display. You cannot use the SUMMARY of DSUMMARY commands to list these results.

The default format, CMPCHG4 formats the result in the form of quadruplets (*fieldname*, *compliance direction*, *baseline value*, *changed value*). If the fieldname is that of a repeated field, the *fieldname* is repeated as often as necessary to list different values. In this situation, the baseline value and the changed value shown on any single line need not be related in any way. Instead the repeat group entries are presented in an unpredictable sequence, as shown in the following example.

```
Fieldname       C Value-1                       Value-2
DFLTGRP           A                             C
CGGRPNM           A                             G
CGGRPNM           B                             E
CGGRPNM                                         F
```

The COMPARE_CHANGES field is sorted on the fieldname, which is in character format. If the field names are the same, they are sorted on the internal value of Value-1, and so on.

The sort order cannot be changed by the SORT modifier or DESCENDING.

For additional information about output formats, see “COMPARE processing output formats: Formatting COMPARE_CHANGES results” on page 829.

Subselect clauses

A subselect clause can be used to display only some entries from a repeated field. For example, you can use a subselect clause to display only those access list entries

with UPDATE access or higher. The subselect clause is most useful when the repeat group has many instances, of which only a few are of interest.

Only the ACL, CONNECTS, CUSTOM_DATA, and USR fields can be used for a subselect clause. Only the subselect CUSTOM_DATA and USR can be used on a LIST command. All subselect variables can be used on SORTLIST and DISPLAY commands. The EXPLODE, RESOLVE, EFFECTIVE, and TRUST modifiers can be used with the subselect ACL.

A subselect clause is like a SELECT, EXCLUDE, or WHERE clause in that it allows the following selection constructs: string match, pattern match, substring match, flag values, date values, authority level match, and access level match. Most tests can specify a single value or a list of values. However, a subselect clause tests on fields that occur within a single repeat group entry: The entire subselect clause is evaluated against each repeat group entry in isolation, so that, an AND condition matches only if there is an entry for which both of its parts are true simultaneously. The fields and subfields that can be used in a subselect clause are different from the fields that can be used in a SELECT statement. The subselect fields are described in Table 291.

Note: If a DEFINE ... SUBSELECT statement also contains a WHERE clause, the WHERE clause follows the normal rules for SELECT statements, not the rules for subselect clauses.

Some CUSTOM_DATA, ACL, and USR subselect clauses can also be used directly on the SELECT and EXCLUDE commands. See "SELECT/EXCLUDE ACL(...)" on page 890, "SELECT/EXCLUDE CUSTOM_DATA(...)" on page 890 and "SELECT USR(...)" on page 892.

Table 291 lists the fields that can be used with subselect ACL. The sample output following the table shows the ACL columns referenced in the table.

Table 291. ACL subselect - available fields

Field	Type	Meaning
ACCESS	access level	Access level as shown in the '*Access*' column. Defined for all repeat group entries.
GROUP	string	Group ID on an access list. For a normal (not exploded or resolved) access list, this is the ID as shown in the **ACL** *id* column, where the **User** column displays -group-. This field is not defined for those entries where the ACL ID is a user or is undefined.
ID	string	ID on an access list. This is the unexploded and unresolved ID, as shown in the **ACL** *id* column. This field is defined for all repeat group entries.
USER	string	User ID on an access list. For an exploded or resolved access list, this is the id as shown in the left column (**User**). This field is not defined for those entries where the ACL ID is a group or undefined.
WHENCLASS **WHENCLAS**	string	Class name used in a conditional access list. Only exists for those repeat group entries that have a conditional access list. Shown as part of the **When** column.

Table 291. ACL subselect - available fields (continued)

Field	Type	Meaning
WHENPROF **WHENPROFILE**	string	Profile or program name used in a conditional access list. This entry only exists for those repeat group entries that have a conditional access list. Shown as part of the **When** column.

Since ID acts on the unresolved and unexploded access list, it cannot be used to select on operations access. To only view operations access–including group operations access–, specify a subselect on ACCESS=ALTER-O.

The following sample output shows ACL fields and columns.

```
newlist
 s key=sysappl.cnracf.**
 sortlist key(20) acl(sort)
Profile key          User     Access  ACL id   When
SYSAPPL.CNRACF.**    -group-  READ    C##ACONF
                     -group-  READ    C##ARACF
                     -group-  READ    SYSBASE
                     -group-  READ    SYSSECUR
                     C##AINT  READ    C##AINT  PROGRAM  CNRACF
                     R##BDAG  UPDATE  R##BDAG  PROGRAM  CNRACF
                     R##PBRP  READ    R##PBRP
                     R##PROB  ALTER   R##PROB
                     R##PSEC  UPDATE  R##PSEC
                     R##PTST  READ    R##PTST  PROGRAM  CNRACF
```

Table 292 lists the fields that can be used with subselect CUSTOM_DATA.

Table 292. CUSTOM_DATA subselect - available fields

Field	Type	Meaning
CSKEY	String	Name of custom field
CSTYPE	Custom field type	The type of the custom field. Possible values are as follows: • Char • Num • Hex • Flag
CSVALUE	Character string, number, hexadecimal string, or flag	The value of the custom field. Because the CSVALUE field value is always handled as characters, you are likely to use a hex notation for the comparison value: For a hex string, you can use hexvalX. For example, for a numeric value of 255 you can use FFX and for flag fields you can use 80X to select true. Character fields can be selected in the normal manner.

The following sample output shows the fields in the CUSTOM_DATA repeat group. For the SORTLIST command, the individual fields in the CUSTOM_DATA group are shown because they most clearly illustrate the three fields available for the subselect clause. However, the default formatting for the CSVALUE field is CHAR, which means that for NUM, HEX and FLAG type fields, the value shown would consist of

non-printable characters. Instead of non-printable characters, the following example uses HEX format. This is also the only value that can consistently be used in the subselect CUSTOM_DATA for CSVALUE.

The following sample output shows the fields in the CUSTOM_DATA repeat group. The ouput is sent to separate fields in the group because there is no field that contains all columns.

```
 newlist type=racf
 select key=crmbsg1 class=user segment=csdata
 sortlist cskey cstype csvalue(hex)

Fldname  Type Custom field data
PHONE    CHAR F1F2F360F1F1F2F9F3F1F2
EMAIL    CHAR 8594979396A885857C85A781949793854B839694
EMPLNO   NUM  F5F2F7F7F1F1
DEPT     CHAR C6D6E4E3D1C5E2
```

An alternative method to display the same information would be to use the special output format CSVALUE for the CUSTOM_DATA field.

```
newlist type=racf
 select key=crmbsg1 class=user segment=csdata
 sortlist cskey cstype custom_data(csvalue)

Fldname  Type Custom field data
PHONE    CHAR 123-1129312
EMAIL    CHAR employee@example.com
EMPLNO   NUM  527711
DEPT     CHAR FINANCE
```

In most situations, a subselect for CUSTOM_DATA can effectively be replaced by a select and sortlist/display on the csname as shown in the following example.

```
newlist type=racf
 select key=crmbsg1 class=user segment=csdata EMPLNO=527711
 sortlist key emplno(8) dept

Profile  Emplno  Dept
USER123  527711  FINANCE
```

The following table lists the fields that can be used with subselect CONNECTS.

Table 293. CONNECTS subselect - available fields

Field	Type	Meaning
GROUP	string	Group in a connect instance. For a CONNECTS instance that is part of a group profile, this is the profile key; for a CONNECTS instance that is part of a user profile, this is a group the user is connected to, as listed in the "User/Grp" column.
GRPADSP	flag	Group-ADSP attribute, as listed in the "AG" column.
GRPAUD	flag	Group-auditor attribute, as listed in the "SOA" column.
GRPAUTH	connect authority	The connect authority (JOIN, CONNECT, CREATE, USE), as listed in the "Auth" column.
GRPGRPACC	flag	Group-grpacc attribute, as listed in the "AG" column.

Table 293. CONNECTS subselect - available fields (continued)

Field	Type	Meaning
GRPOPER	flag	Group-operations attribute, as listed in the "SOA" column.
GRPRESUMEDT	date	Connect-resume date, as listed in the Resumedt column.
GRPREVOKE	flag	Indicates whether the connect is revoked, using the unload date as a reference. Listed in the 'R' column.
GRPREVOKEDT	date	Connect-revoke date, as listed in the *Revokedt* column.
GRPSPEC	flag	Group-special attribute, as listed in the "SOA" column.
GRPUACC	access level	Group-UACC, as listed in the "UACC" column.
USER	string	User in a connect instance. For a CONNECTS instance that is part of a user profile, this is the profile key; for a CONNECTS instance that is part of a group profile, this is one of the users connected to the group, as listed in the "User/Grp" column.

The following sample output shows the CONNECTS field and its columns referenced in Table 293 on page 758.

```
newlist type=racf
 select key=ibmuser class=user
 sortlist connects
User/Grp Auth    R SOA AG Uacc    Revokedt    Resumedt

OMVGRP   USE              NONE
SYSCTLG  JOIN    R        READ
SYS1     JOIN      S      READ
VSAMDSET JOIN             READ    01 Jan 1996
```

Table 294 lists the fields that can be used with subselect USR. For more information about the USR field and its use by CKGRACF, and possible values of USR fields values referenced in Table 294, see Chapter 13, “SELECT/LIST Fields,” on page 953.

Table 294. USR subselect - available fields

Field	Type	Meaning
CKGAUTHOR	char	Requesting user of a queued command, if the USR field is a CKGRACF queued command; undefined otherwise.
CKGCHGDATE	date	Last change date of a queued command. if the USR field is a CKGRACF queued command; undefined otherwise.
CKGMULTI	char	Multiple-authority setting, if the USR field is a CKGRACF multiple-authority setting; undefined otherwise.
CKGREQUEST	date	Request date of a queued command. if the USR field is a CKGRACF queued command; undefined otherwise.

Table 294. USR subselect - available fields (continued)

Field	Type	Meaning
CKGSCHED CKGSCHEDULE	char	Schedule name, if the USR field is a CKGRACF scheduled revoke/resume action; undefined otherwise.
CKGSTATUS	char	Status of a queued command, if the USR field is a CKGRACF queued command; undefined otherwise.
USRDATA	char	Contents/value of the USR field.
USRFLG	flag	Flag in the USR field. You can either specify a hexadecimal value, or a bitmask.
USRNM	char	Index of the USR field.

Field-based defines

A field-based define is a definition where a variable is defined as another field. In its simplest form, the variable behaves exactly as the original field. You can add an overriding length, format, or header to get a new variable that behaves like the original field, but has a different layout or header. Finally, you can use any field value manipulation function such as `SUBSTRING` or `LOOKUP` that uses the original field as its source, and puts the result in the variable. (See "Field value manipulation") A field-based define uses the `DEFINE AS` command syntax, as follows:

```
define usdate(8,usdate) as date
define logged(hdr$blank,6,'Logged') as uaudit
define dflt_owner as dfltgrp:owner
```

A variable so defined can be used in SORTLIST, DISPLAY, and SUMMARY commands. These variables can also be used in SELECT/EXCLUDE statements. In the preceding examples, USDATE would be a useful shorthand if your reports always contain DATE(8,USDATE). Similarly, oft-repeated expression using look ups can best be written as defined variables.

Field value manipulation

In CARLa several functions for field value manipulation are available. These functions are designed to allow selection and reporting on only parts of a field, or on values based on, but not containing the field value (indirect references). These functions include the following:

CONVERT

When a character format field contains a date or number, normal processing always processes the field value as a string of characters. However, sometimes it is useful to process dates and numbers as values rather than strings. For example, if you have a character string that has date and time information, you might want to process the date and time parts of the string separately. The product provides the `CONVERT` function for this purpose.

The `CONVERT` function has the following syntax:

```
CONVERT(field, input format, internal format)
```

If a default internal format has been specified, you can use the following syntax:

```
CONVERT(field, input format)
```

The input format specifies the way the character format field currently contains the data. For example, the field might be a human-readable decimal field, or a packed-decimal field. The program uses the internal format to determine the correct selection and sort procedures for the data. An internal format also corresponds to a default output format.

The following list provides the input formats, the internal formats they can be converted to, and the default output format for printing the internally formatted field.

DATETIME (default)
In this input format, both the date and the time part of the string are in a sortable form. This format can be printed with most date and time formats. The supported format for date values can be found in "Date fields" on page 903.

The following internal formats are available to convert this format:

- DATE

  The date part of the field only. A value in this format field can be printed with the output formats ACF2DATE, DATE (default), JULDATE, USDATE, $DATE.
- SMFTIME

  The time part of the field only. A value of this format can be printed with the SMFTIME output format only. The SMFTIME output format is the default format.
- WEEKDAY

  The day of the week. A value of this format can be printed with the WEEKDAY output format only. The WEEKDAY output format is the default format.

The following processing rules apply to this format:

- The time is expected in the following format: hh:mm:ss:cc format. Hours and centiseconds can also be a single digit; seconds and centiseconds are optional. Instead of the colon (:), any single, non-space, non-digit separator can be used.
- Any text following the DATETIME specification is ignored.

DECIMAL
This input format is a human readable decimal integer, containing no commas or dots. The default internal format is DECIMAL, which is a standard numeric field that can be printed with the output formats DEC (default), DEC$BLANK, DEC$NO, and NUM.

PACKED
This input format is a packed decimal field as defined in the z/OS Principals of Operations. The default internal format is DECIMAL which is a standard numeric field. This internal format can be printed with the output formats DEC (default), DEC$BLANK, DEC$NO, and NUM.

SMFTIMESTAMP
This input format is the full time stamp as SMF stores it. This value can be printed with most date and time formats.

INTERNALDATETIME
This input format is the zSecure internal representation of the date and time. Using this format, you can convert a field defined as DATETIME into one of the following internal formats. The possible internal formats are as follows:

DATE
The date part of the field. This field can be printed with the output formats ACF2DATE, DATE (default), JULDATE, USDATE, $DATE.

SMFTIME
The time part of the field. This internal format can be printed with the SMFTIME output format only. The SMFTIME output format is the default format.

SMFTIMESTAMP
The date and time can be printed in SMF time stamp format.

WEEKDAY
The day of the week. This internal format can be printed with the WEEKDAY output format only. The WEEKDAY output format is the default format.

The following example shows the code to convert the input field to internaldatetime format for internal processing to be printed in the SMFTIMESTAMP format.

```
def type=svc mth("Mth",month,3)
convert(collect_datetime,internaldatetime,SMFTIMESTAMP)
```

LASTQUAL
Refers to the last qualifier in a field value. If the field value is aaa.bbb.ccc, the last qualifier is ccc. The syntax is LASTQUAL(*field*), where *field* is the field name.

PARSE
A particular section of a field, recognizable by unique identifiers before and after it, can be found with the PARSE operation. It has the following syntax:

```
PARSE(field, start separator[, end separator])
```

The *field* specified must have a character format. The *start separator* is the text right before the section wanted. The *end separator* is the text after the section wanted. For example, assume a field named DATA containing several items of information about a person: the name, function, and department. It is structured as follows:

```
Name: Doe, J.; Function: programmer; Dept: Data Processing;
```

or

```
Function: programmer; Dept: Data Processing; Name: Doe, J.;
```

```
PARSE(DATA,'Name: ',';')
```

will contain Doe, J.

If the start separator occurs more than once in the field processed, the first occurrence is used to calculate the field value to be returned. If the end separator is omitted, the returned value consists of all characters after the start separator to the end of the field.

PICT
Defines the character type of each character in the field value. The maximum supported field value length is 256 characters. The function returns a character string where each character represents the character type in the original field value. The possible types are:

- @ - represents an alphabetic character (A-Z, a-z)
- # - represents a number character ((0-9)
- $ - represents a punctuation character

- <space> represents a space character
- .(dot) represents all other characters

QUALIF
An index number from 1 to 123 that represents a qualifier segment of a field value. The syntax is QUALIF(field,index) where field is a name of a NEWLIST type in the form TYPE=*type*. The index is a number that represents the position of the qualifier segment in the name. If the field value is aaa.bbb.ccc, the index number 1 represents aaa.

QUALNUM
Calculates the number of qualifiers in the field value. The syntax is QUALNUM(field).

SUBSTRING, SUBSTR
Substrings can be generated from character fields using the SUBSTRING operation. The substring can have the following following formats:

- SUBSTRING(*field*,*startpos*,*length*)
- SUBSTRING(*field*,*startpos*:*endpos*)
- SUBSTRING(*field*,*startpos*)

The *field* specified must have a character format. The *startpos* is the start position where the substring of the field may start; the first character in the field has position 1. You can specify a *length* or an *endpos*. If you specify a length, it must be at least 1. If you specify an *endpos*, it must be equal to, or greater than, the *startpos*. If neither *length* or *endpos* are specified, the substring continues until the end of the field.

For example, consider a site that has defined the user IDs in the format DDGGNN, where DD is the department, GG the workgroup, and NN the user number in the group. The department can be specified as either SUBSTRING(USER,1,2) or SUBSTRING(USER,1:2). The group can be specified as SUBSTRING(USER,3,2) (using a *length*) or SUBSTRING(USER,3:4) (using an *endpos*).

On an ISPF display, variables defined as substrings with an output format of CHAR or ASIS are modifiable if the source field was modifiable. Multiple substrings may be on the display at the same time. They may even overlap, but any actual updates may not conflict with any of the other places on the screen where the same information is being displayed. Multiple substrings of one repeat group field may only be present on the same line of the detail display.

WORD
A particular word can be found in a character field with the WORD operation. This has the following syntax:

```
WORD(field,number[,delimiter(s)])
```

The *field* specified must have a character format. The *number* is the number of the word wanted (that is, the second word in the sentence for *number*=2). The delimiter can be a single character, possibly between quotations (necessary if you want to specify a comma or another type of quotation), or a string of up to 40 characters. Each occurrence of (one of the) character(s) you specified will indicate the start of the next word in the sentence. If you omit the delimiter, the words are separated by *one or more* blanks and blanks occurring at the start of the record will be skipped. When a delimiter is followed immediately by a quotation (either single, left or back quotation), the scan will first search for the balancing quotation and only the first delimiter thereafter will start the next word. If that delimiter immediately follows the balancing quotation (for

example, the result is a properly quoted string without further suffix), the quotations are stripped off. Otherwise, the quotations are left in place.

Some examples:

WORD(field,n) returns the nth blank delimited word, so:

```
field = "    one two   three 'four and five'"
```

results in:

```
WORD(field,1) = "one"
WORD(field,2) = "two"
WORD(field,3) = "three"
WORD(field,4) = "four and five"
WORD(field,5) = ""
```

WORD(field,n,delimiter) returns the nth token from the text string, where each occurrence of the delimiter signals the end of a token, so:

```
field = ";;one two; three;'four;five' "
```

results in:

```
WORD(field,1,';') = ""
WORD(field,2,';') = ""
WORD(field,3,';') = "one two"
WORD(field,4,';') = " three"
WORD(field,5,';') = "four;five"
WORD(field,6,';') = ""
```

Combining the functions

All the functions mentioned above can be combined to create complex expressions. If a field has been divided by semicolons and in the third part both a price and a comment are present in a random order, you could specify the price as follows:

```
PARSE(WORD(field,3,';'),'$',' ')
```

Taking just the dollar part, and storing it as an integer would be:

```
CONVERT(PARSE(WORD(field,3,';'),'$','.'),DECIMAL)
```

The email address of the salesman, whose LID or user ID is in the second part of the field would be

```
WORD(field,2,';'):EMAIL.USER.ADDRESS
```

Indirect reference or lookup

An indirect reference or lookup is the action of retrieving a different field from a database, based on the value of a base field. The general syntax for this is:

```
[basefield]:lookup-specification[:lookup-specification ...]
```

So an optional base field specification, followed by one or more levels of lookup. If the base field is omitted, we call that an object property lookup or implicit lookup operation. If the base field is present, we call it an explicit lookup operation and it can be an ID lookup, CLASS property lookup, SYSTEM property lookup, or a `deftype` lookup. If more than one lookup operator is present, the operation is known as a multi-level lookup. The lookup specification itself can contain one, two, or three qualifiers separated by a dot:

```
targetfield | type.targetfield | type.keyfield.targetfield
```

There is a difference between lookup in a SELECT or EXCLUDE statement and lookups in a LIST family command. For a SELECT type lookup to work, the data must be read into the program before the SELECT is executed. For a LIST family lookup this prerequisite does not apply. For DEFTYPE lookups, zSecure

can automatically determine the most optimal point where to read the data. However, this automation is not supported if a newlist of type A does a lookup to newlist type B in the SELECT statement, and a type B SELECT statement does a lookup to type A.

You can specify the following types of indirect references or lookups: Object property lookup, ID lookup, CLASS property lookup, SYSTEM property lookup, and deftype lookup.

Object property lookup

Lookup to request properties of a (security-related) object, written as

```
:targetfield
```

Object property lookups are currently only supported from the following NEWLIST types: SMF, RACF, TRUSTED, and REPORT_SCOPE. The target field will be retrieved from the security database. The security database (RACF) is determined automatically based on the available information, in CKFREEZE files for example. In anticipation of future versions, you can specify RACF as a target NEWLIST type in an object property lookup. However, this specification is currently ignored. For RACF systems, the key linking the target field to the source object consists of the combination of the complex, class, and RACF profile covering the resource. The target field can only be an existing field in the target database. Currently, if the target field specification is ambiguous (for example, present in multiple segments), the field value that is shown is not predictable. Defined variables are not supported.

Example object property lookup (RACF)

```
newlist type=smf
  select exists(profile)
  display resource :instdata
  dsummary class * profile
```

Example cross-segment object property lookup (RACF)

```
newlist type=racf
  s class=dataset segment=dfp
  display key complex :instdata
  dsummary resowner
```

Example object property lookup (RACF)

```
newlist type=report_scope
  report scope=ibmuser
  display key(firstonly) complex :racf.instdata
  dsummary via
```

ID lookup

The ID lookup is a lookup where the base field is interpreted as a user or group, and the target field is retrieved from that user or group. Use the following code to specify the base and target field values for the lookup:

```
basefield:targetfield
```

ID lookups are supported from all NEWLIST types. The target field is retrieved from the security database. The security database (RACF) is determined automatically, based on the available information in CKFREEZE files for example. Here, the key (source) of the lookup is a user ID or group ID. That is, the value of the base field padded to 8 characters is used to look up a user or group in the same complex as the record. The target field cannot be a variable. Currently, if the target field specification is ambiguous (for example, present in multiple segments), the field value that is shown is

not predictable. The id lookup can be repeated to create a multi-level lookup. It can also be added to extend any of the other lookup types to create a multi-level lookup.

Example id lookup (RACF)

```
newlist type=racf
  s  c=group s=base
  d key(8) supgroup owner owner:name owner:instdata
```

Example multi-level id lookup (RACF)

```
newlist type=racf
  s c=dataset s=base
  d class key owner owner:owner owner:owner:instdata
```

CLASS property lookup

The CLASS property lookup is an explicit lookup where the value for the base field is interpreted as a class name and an arbitrary class property can be used as the lookup result. This is done by specifying lookup target NEWLIST type CLASS and target NEWLIST key field CLASS. Use the following syntax to specify the base and target field values for a CLASS property lookup:

```
basefield:type.keyfield.targetfield
```

For instance to see whether a CLASS used in the past is now inactive, you could specify:

```
newlist type=smf
  select class:class.class.active=no
```

The CLASS properties are taken from the default system for the complex that the record belongs to, not necessarily from the system the record pertains to; typically, the system is the same for both. The CLASS property lookup is supported for the following NEWLIST types: RACF, TRUSTED, ACCESS, RACF_ACCESS, SMF, ROUTER, R_SCOPE, or R_PROFILE.

SYSTEM property lookup

The SYSTEM property lookup is an explicit lookup where the value for the base field is interpreted as an SMF ID, generally the CARLa SYSTEM field within the current complex and version. This is done by specifying lookup target NEWLIST type SYSTEM and target NEWLIST key field SYSTEM. An arbitrary non-repeating class property can be used. Use the following syntax to specify the base and target field values for the SYSTEM property lookup:

```
basefield:type.keyfield.targetfield
```

For example to select SMF records from RACF systems based on the &SYSCLONE system variable:

```
newlist type=smf
  select system:system.system.sysclone='01'
```

The SYSTEM property lookup is supported for the following NEWLIST types: ACCESS, CONSOLE, DYNEXIT, EXIT, IP_AUTOLOG, IP_INTERFACE, IP_NETACCESS, IP_PORT, IP_ROUTE, IP_RULE, IP_STACK, IP_VIPA, MOUNT, PPT, R_AC1, R_PADS, R_STC, RRSFNODE, SENSDSN, SMF, TRUSTED, and UNIX.

deftype lookup

This a lookup to a NEWLIST type define via the DEFTYPE command. All qualifiers in the lookup specification must be spelled out. The syntax is:

```
basefield:type.keyfield.targetfield
```

This requests an indirect reference to a database defined with DEFTYPE. Both the key field and the target field can be variables. The value of the base field in the source record is used as key field to locate the value of the target field. See the <deftype> field description for an example (on page 767).

For multi-level lookups, the lookups beyond the first one are by definition explicit lookups (either an ID lookup, or a deftype lookup), The base field specified must have a character format. No other limitations apply. Most fields are supported as a target field, except that the lookup returns only one value for a repeated field. Which value of a repeated field (the first, the last, or an arbitrary one) will be returned is unpredictable. The current selection of the returned value in a repeat group is not an intended interface. The NEWLIST types supported are:

RACF
Object Property Lookups retrieve information from the profile covering the resource object in the source NEWLIST type. ID Lookups treat the base field as a user ID or groupid and retrieve information from the user or group profile. Most fields of the target profiles are supported. For repeat group fields, only one value will be returned. Which repeat group entry will be used is unpredictable.

<deftype>
Indirect references are possible to any field of databases defined with the DEFTYPE command. The *newlist* type is the type specified on the DEFTYPE command, the *keyfield* is the defined field that should contain the value that corresponds to the value in the *basefield* and the *targetfield* is the defined field that contains the value referenced.

For example, a database has been allocated that contains two fields: the or user ID and the email address of that person. It has been defined with DEFTYPE TYPE=EMAIL and the two fields are defined as USER and ADDRESS. To report on the address of the users in the SMFUSERID field the specification would then be:

```
SMFUSERID:EMAIL.USER.ADDRESS
```

The lookup is performed without case translation. Consequently, the lookup value must match the case of the key-values present in the external lookup file. As most fields are uppercase, it is a good idea to use uppercase key-values for the email address lookup.

Defining fields in SMF records

In CARLa several functions for the retrieval of fields from an SMF record are available. These functions are the following:

RACF_SECTION
The RACF_SECTION function retrieves values described by a RACF relocate section within the SMF record. This is a possibly repeated section available only in RACF processing records (SMF 80, 81 and 83). Each section type is indicated by a number in the range 1 to 65535. The RACF_SECTION function has the following syntax: RACF_SECTION(*code*) or RACF_SECTION(*code,offset within section,length*). All values are in decimal; offset 0 indicates the start of the section. The version with one parameter uses the whole of the repeated section; the other version uses a specific part of the section. When used, the RACF_SECTION reads one value from the SMF record for each relocate section

in the record (it will not read beyond the end of the SMF record). RACF relocate sections are documented in the "Security Server RACF Macros and Interfaces" manual.

For example, the data set level field in a RACF processing record is described by relocate section 5. You can define this field using the following construction:

```
define type=SMF dsnlevel(3,dec) as racf_section(5)
newlist type=SMF
select dsnlevel>1
sortlist date time dataset dsnlevel
```

SMF_FIELD

The SMF_FIELD function retrieves values from a constant offset within the SMF record. It has the following syntax: SMF_FIELD(*offset in record,length*). Both the offset and the length are in decimal; offset 0 indicates the start of the record (the length field). When used, the SMF_FIELD reads a value from the SMF record at the indicated offset, with the indicated length (it will not read beyond the end of the SMF record, but truncate the field instead). Offsets and lengths of SMF fields are documented in the "MVS System Management Facilities (SMF)" manual.

For example, the DATE field in an SMF record resides at offset 10 and has length 4. You can define this field yourself using the following construction:

```
define type=SMF mydate(date) as smf_field(10,4)
newlist type=SMF
select mydate=01jan1996
sortlist mydate
```

The following example shows how to make a dump of SMF records.

```
newlist type=smf t='hex dump of smf records'
define smf_record as smf_field(0,32767)
sortlist recno smf_record(dump)
```

SMF_SECTION

The SMF_SECTION function specifies retrieves values described by a so-called self-defining section within the SMF record. This is a triple of (offset,length,number) values describing a repeated section in an SMF record, e.g. the product section in SMF 30. The SMF_SECTION function has the following syntax: SMF_SECTION(*offset to triple*) or SMF_SECTION(*offsettotriple, offset within section,length*). All values are in decimal; offset 0 indicates the start of the record (the length field) or the start of the triple. The version with one parameter uses the whole of the repeated section; the other version uses a specific part of the section. When used, the SMF_SECTION reads one value from the SMF record for each such triple in the record (it will not read beyond the end of the SMF record). Offsets and lengths of SMF fields are documented in the "MVS System Management Facilities (SMF)" manual.

For example, the subsystem section field in an SMF 30 record is described by a triple at offset 24. The subsystem or product id resides at offset 6 and has length 8.

```
define type=SMF id(char) as smf_section(24,6,8)
newlist type=SMF
select id=smf
sortlist date time jobname id
```

All three types of construct can then be used in SELECT/EXCLUDE processing, and in output processing. The overriding format specified (CHAR, DEC, or DATE in the preceding examples) determine both the input format and the output format. If the field is only valid under certain circumstances, these can be specified using a

WHERE clause in the DEFINE. The field is only available if the WHERE clause is true; otherwise it is missing. For instance, the specification of SMF 30 can be added to the definition. The following example shows how the field can be defined and used:

```
define id(char) as smf_section(24,6,8) where type=30
newlist type=SMF
select id=smf
sortlist date time jobname id
```

Tutorial: Reporting on a user log

In the following section we will show you how the define statements needed to analyze the HTTP error log were built. You can use this as a guideline when creating the CARLa for reporting on any log files needed. We will start with the simplest case, and add complications and their solutions as we go.

First we issue a DEFTYPE command to give our new NEWLIST type a unique name.

```
deftype type=$HTTPERROR
```

The $ character has been included to ensure that there is no predefined type with the same name. Any national character (@, $ or #) can be used for that purpose.

Next we take a look at a single record in the HTTP error log. The simplest looks as follows:

```
[04/May/2001:08:22:54 -0100] IMW0487E Persist timer expired while
   waiting on client 10.0.96.4
```

A date, time and time zone specification between square brackets, followed by the error message issued.

A first shot at parsing this could be

```
define type=$HTTPERROR datetime as parse(record,'[',']')
define type=$HTTPERROR error as parse(record,']')
```

This creates two fields. DATETIME will contain the text present between the square brackets, and ERROR will contain everything after the closing bracket up to End-Of-Line. Both fields can be used directly, but they can still be improved. The ERROR field as we have defined it now still starts with a blank, and the DATETIME field will be treated as if it was a normal string of text. It will sort incorrectly, and select functions built specifically for dates and times will not work for it.

Improving the ERROR field is simple. Just include the blank in the starting delimiter.

```
define type=$HTTPERROR error as parse(record,'] ')
```

For the DATETIME field we need to add a convert function to change the text field to a date/time field.

```
define type=$HTTPERROR datetime as convert(parse(record,'[',']'),datetime)
```

Now functions like select will treat this field as a time stamp, thus allowing you to select on it and sort it at will.

However, we have lost some information: the time zone is not remembered in datetime convert processing. If we still want to report it, we need to create a new

field for it. The time zone is everything after the blank in the string between the square brackets. We could find this with another parse command, but this time we will use word to do it.

```
define type=$HTTPERROR timezone as word(parse(record,'[',']'),2,' ')
```

The parse still gives us the text between the brackets, but now we use the word function to split it in two parts: everything before the blank, and everything after it. Our field will be the second part.

There are several other possibilities for the convert function as well. If you want to report on the day of the week the record was written, you could use define

```
type=$HTTPERROR weekday as convert(parse(record,'[',']'),datetime,weekday)
```

There are also records in the log that look different:

```
[04/May/2001:08:16:48 -0100] [IMW0210E MULTI FAILED] [host: 10.0.96.4
     user:c####r1] /c####/AutoHelpdesk.html
[04/May/2001:08:26:34 -0100] [IMW0196I NOT AUTHENTICATED]
     [host: 10.0.96.4] /c####/Helpdesk.htm
[04/May/2001:11:25:20 -0100] [IMW0193I OK] [host: 10.0.96.2
     user: c####r1 referer: https://10.0.1.22/c####/Helpdesk.html] IMW0532E
 ReadContent..Premature End Of File on socket 23 - reason 1
```

There are several differences here: a message in a second set of brackets, some identification in a third set and either a file or a second message as final part of the record.

To get the error that is shown in the second set of brackets we can use a parse with a start delimiter of ' [' (blank bracket), to differentiate the opening bracket of the second set from that of the first. We can also separate the record into different parts with word and the open bracket as delimiter. We will use the latter method, because it is easier to extend for the third set of brackets. There are two issues with this method. One is that we need to keep in mind that the first open bracket, even though nothing precedes it, separates the first "word" of the record from the second, so that for the text after the second bracket we need the third "word". The other is that we still need to trim the closing bracket and its trailing space from our text. We do this with another word function, this time with the close bracket as delimiter.

```
define type=$HTTPERROR error2 as
   word(word(record,3,'['),1,']')
define type=$HTTPERROR identifier as
   word(word(record,4,'['),1,']')
```

Now we want to split the identifier in host, user and referrer fields. We do this with a parse, looking for the host: text. If we include the blank in our starting delimiter, we can use the blank preceding the next identifier as our ending delimiter.

```
define type=$HTTPERROR host as
   parse(word(word(record,4,'['),1,']'),'host: ',' ')
define type=$HTTPERROR user
   as parse(word(word(record,4,'['),1,']'),'user: ',' ')
define type=$HTTPERROR referer
   as parse(word(word(record,4,'['),1,']'),'referer: ',' ')
```

The tail of the record can be picked up with another word call, taking everything after the third closing bracket. To remove the leading blank from the field we need

to use the substring function. We cannot simply add the blank to the delimiter like we did for the parse earlier because word only accepts a single character as delimiter.

```
define type=$HTTPERROR tail as substring(word(record,4,']'),2)
```

The substring specification here is: from the second character until End-Of-Line.

Actually, we don't want to call this field tail. In some cases it is an error message, and in some cases it is a file. So how do we differentiate between the two? Since file names can contain all characters that the error message can contain, this is easier said than done. In our log, all files are shown with absolute pathnames, so start with /, and all messages start with IMW. We could use either of these criteria, but we need to keep in mind that these are not guaranteed to be true. For now we'll use the slash to positively identify a file and keep an eye out for anomalies.

```
define type=$HTTPERROR firstchar as
   substring(word(record,4,']'),2,1)
```

We define a field FIRSTCHAR that contains only the one character we will use for the differentiation. We do that by specifying a length of one on the substring. This field can then be used in a where clause.

```
define type=$HTTPERROR file as
   substring(word(record,4,']'),2) where firstchar='/'
define type=$HTTPERROR error3 as
   substring(word(record,4,']'),2) where firstchar<>'/'
```

By now we have defined three error fields while we usually only want to show one message, so we need some more where clauses to make sure only one is actually filled in. Our original ERROR field is only valid when ERROR2 is not present, and we probably do not want to show the OK message in ERROR2 when there is an ERROR3 present. This means we only want ERROR2 when there is no ERROR3, and ERROR only when we have neither.

```
define type=$HTTPERROR error3 as
   substring(word(record,4,']'),2) where firstchar<>'/'
define type=$HTTPERROR error2 as
   word(word(record,3,'['),1,']')where missing(error3)
define type=$HTTPERROR error as
   parse(record,'] ')where missing(error3) and missing(error2)
```

These three fields can then be shown concatenated:

```
   sortlist error3(0) | error2(0) | error(0)
```

The defines as presented here are missing some output modifiers. Ideally, they should have a default format, output length and column header specification. All defines inherit these from the RECORD field except the DATETIME field. The DATETIME field gets the *datetime* format from the convert function and the WEEKDAY, which gets the weekday format. The format inherited from the RECORD field is ASIS, which has specifically been built to keep trailing spaces intact. If you want those trailing spaces trimmed in your output, you should use output format CHAR as shown in this code sample:

```
define type=$HTTPERROR file('Target file' char 30) as
   substring(word(record,4,']'),2) where isfile='/'
```

Another caveat, specific to this example: EBCDIC includes two different sets of square brackets: 1) `x'BA'` and `x'BB'` , and 2) `x'AD' and x'BD'`. When using square brackets in these field value manipulation functions, verify that you are using the set that is actually present in your logfile.

Title, format and output length

The newly defined field will inherit the default values (they can be overridden, see "Parameter syntax: Specifying parameters for LIST/SORTLIST/DISPLAY commands" on page 796) these characteristics from the base field. There are the following exceptions to this:

- Indirect references These fields will have the default output format of the target of the reference.
- Converted fields These fields will have the default output format corresponding with the selected internal format.

Example: Basic summary statistics

The basic use of the DEFINE command for summary statistics is illustrated in the following example:

```
define cnt count                 /* Count selected instances */
define permits sum(aclcnt)       /* Sum of the number of ACL entries */
define maxacl max(aclcnt)        /* Highest number of ACL entries */
define maxacs max(useracs)       /* Highest access of ACL entries */
define frq freq                  /* Relative frequency */
summary class cnt frq permits maxacl maxacs
```

This shows, for each class of profiles, the number of profiles, the total number of entries on all of the access lists in that class, the largest access list, and the highest level of access.

Example: count and sumcount

The following example shows the use of COUNT and SUMCOUNT. As is shown, COUNT indicates the number of instances summarized, and SUMCOUNT indicates the number of distinct cases found.

```
/* Show difference between count and sumcount */
newlist type=racf
 select class=user segment=base mask=utst*
 sortlist class key(8)
 define diff_keys sumcount
 define records  count
 summary class diff_keys * key(6) records
```

```
Class    DIFF_KEY Profil RECORDS  Class    Profile
USER            3              13
                  UTST2$        4
                                   USER     UTST2$S
                                   USER     UTST2$T
                                   USER     UTST2$U
                                   USER     UTST2$V
                  UTST2#        5
                                   USER     UTST2#R
                                   USER     UTST2#S
                                   USER     UTST2#T
                                   USER     UTST2#U
                                   USER     UTST2#V
                  UTST2@        4
                                   USER     UTST2@S
                                   USER     UTST2@T
                                   USER     UTST2@U
                                   USER     UTST2@V
```

Of the thirteen users selected, there are three different cases when using the first 6 characters only.

Example: WHERE clause for summary statistics

The use of a conditional clause is illustrated in the following examples:

```
/* Count selected instances that also have userid=ibmuser */
define cnt count where userid=ibmuser

/* Count frequency of selected instances that also have UACC>=READ */
define uacchigh freq where uacc>=read
summary class cnt uacchigh
```

The variable *cnt* counts the amount of summarized records that have user ID=IBMUSER. Similarly, the variable UACCHIGH describes the relative frequency of occurrences with UACC>=READ among the summarized occurrences.

Example: Boolean variable with SORTLIST

The use of a WHERE clause to define a Boolean variable that can be used with a SORTLIST command is shown in the following example:

```
/* Set variable to TRUE if profile was created in last month */
define recent boolean where creadate>today-31
sortlist profile recent
```

Example: Sharing a WHERE clause

The use of the COUNT, FREQ, and BOOLEAN types with a shared WHERE clause is illustrated in the following examples:

```
/* Variable with WHERE clause that is to be shared */
define recent boolean where createdate>today-31

/* Relative frequency of recent instances */
define recfreq freq(recent)

/* Count the number of selected recent instances */
define reccnt count(recent)
```

In the example, the RECFREQ and RECCNT variables use the WHERE clause defined with the Boolean variable RECENT.

Example: subselect access list

A subselected variable displays only those ACL instances that match the subselect clause. The ACL modifiers EXPLODE (display all possible access), RESOLVE (for each user who has access via the ACL, list the highest access) and EFFECTIVE(as RESOLVE but also include access by other means than via the ACL) can be used, both in the variable definition and on the DISPLAY/SORTLIST (the latter overrides the former). In the following example, only those ACL entries are selected that have an access of UPDATE or higher, or that are conditional access list entries of type PROGRAM. The original access list is shown in the preceding section.

```
newlist
 select class=dataset key=sysappl.cnracf.**
 define demoacl subselect acl(access>=update or whenclass=program)
 display key(20) demoacl

Profile key          User     Access  ACL id   When
SYSAPPL.CNRACF.**    R##PSEC  UPDATE  R##PSEC
                     R##PROB  ALTER   R##PROB
                     R##BDAG  UPDATE  R##BDAG  PROGRAM  CNRACF
                     C##AINT  READ    C##AINT  PROGRAM  CNRACF
                     R##PTST  READ    R##PTST  PROGRAM  CNRACF
```

Example: subselect user in access list

In the following example, all data set profiles are selected that have user IBMUSER in their access list. Of those profiles, the exploded access list is subselected for user IBMUSER; this displays all types of access the user has on the profile. RESOLVE would have displayed the highest access of IBMUSER; if no output modifier had been used, only the access list entries for IBMUSER would have been displayed.

```
newlist
 select class=dataset userid=ibmuser
 define ibmacl(explode,sort) subselect acl(user=ibmuser)
 display key(20) ibmacl
```

```
Profile key          User     Access  ACL id   When
C##HANS.TEST.BIG.PRO IBMUSER  NONE    IBMUSER
IPCS.*.**            IBMUSER  ALTER   IBMUSER
                     IBMUSER  ALTER   SYS1
SYS1.*.**            IBMUSER  ALTER   IBMUSER
                     IBMUSER  ALTER   SYS1
SYS1.BRODCAST        IBMUSER  ALTER   IBMUSER
SYS1.CMDLIB          IBMUSER  ALTER   IBMUSER
SYS1.CMDPROC         IBMUSER  ALTER   IBMUSER
SYS1.COBLIB          IBMUSER  ALTER   IBMUSER
SYS1.DIRACC          IBMUSER  ALTER   IBMUSER
SYS1.DIVERSEN.*.**   IBMUSER  ALTER   IBMUSER
SYS1.DUMP*.**        IBMUSER  ALTER   IBMUSER
SYS1.LOGREC          IBMUSER  ALTER   IBMUSER
SYS1.MAN*.**         IBMUSER  ALTER   IBMUSER
SYS1.PLI*.**         IBMUSER  ALTER   IBMUSER
SYS1.PRODUCTS.*.**   IBMUSER  ALTER   IBMUSER
SYS1.RC.HELP         IBMUSER  ALTER   IBMUSER
SYS1.UADS            IBMUSER  ALTER   IBMUSER
```

Notes: The selection only selects profiles that have IBMUSER on the access list. Profiles where IBMUSER does not have direct access, e.g. because he only has indirect access through a group id on the access list, are not included. To select all profiles and all reasons that a user has access, use the NEWLIST SCOPE parameter, e.g. SCOPE=IBMUSER, or use the REPORT SCOPE.

Example: subselect connect instances

In the following example, all user profiles are selected that have one or more group-SPECIAL attributes. Of the group-connects, only those that are group-special are printed.

```
newlist
 select class=user grpspec
 define specs subselect connects(grpspec)
 display key(8) specs
```

```
Profile  User/Grp Auth    R SOA AG Uacc    Revokedt    Resumedt
UCNGADM  GCNGTG   USE       S A    NONE
UCNG002  GCNGT    USE       S      NONE
UTST2#R  GROUP1   USE     R S A AG NONE
```

The next example selects all user profiles that have 2 or more group-connections. One of these is always the default-group. The query displays only the non-default group connections. Note the use of a field-to-field comparison instead of a field-to-constant comparison.

```
newlist
 select class=user congrpct>1
 define nondflt(8) subselect connects(group<<>>user:dfltgrp)
 display key(8) dfltgrp nondflt
```

```
Profile  DfltGrp  User/Grp
IBMUSER  SYS1     OMVGRP
                  SYSCTLG
                  VSAMDSET
UCNGADS  GCNGTG   SYS1
UTST2$T  GROUP1   VSAMDSET
UTST2$U  GROUP1   VSAMDSET
UTST2$V  GROUP1   VSAMDSET
UTST2#T  GROUP2   VSAMDSET
UTST2#U  GROUP2   VSAMDSET
UTST2#V  GROUP2   VSAMDSET
```

Example: subselect custom field

The following example shows data all users in the department that is stored in the custom field DEPT.

```
newlist type=racf
define department(8) subselect custom_data(cskey=dept)
select class=user segment=csdata
sortlist key(8) department
```

Notice however that this simple example could have been coded more easily as:

```
newlist type=racf
select class=user segment=csdata exists(dept)
sortlist key(8) dept
```

Example: summary statistics with WHERE clause

The following example shows the use of WHERE clauses for variables used with a SUMMARY command. Summary variables with a WHERE clause are updated only if the WHERE clause is true, whereas variables without a WHERE clause are updated for each occurrence summarized.

```
newlist type=racf
 define class#('#profiles' 9) count
 define class@('%profiles' 9) freq
 define generic#('#gen in class' 13) count where generic
 define generic@('%gen in class' 13) freq where generic
 summary class class# class@ generic# generic@
```

Example: Defining a <deftype> file

```
deftype type=email
define type=email user as word(record,1,' ')
define type=email address as word(record,2,'40'X)
```

DEFTYPE

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

The DEFTYPE command can be used to define a NEWLIST type which can then be used on the following commands:

1. ALLOCATE to allocate the files which are to be read for the new type
2. DEFINE to specify the fields that can be used in reporting on this data
3. NEWLIST to report on the contents of the new type of data
4. indirect references to this data

The parameters recognized by the DEFTYPE command are the following:

ABBREV2= *abbreviation*
This optional parameter sets the two character abbreviation used to create default ddnames for the files that will be allocated. The DDnames are of the format CKR@*aaxx* where *aa* is the abbreviation specified and *xx* is a counter from 0 to 99 too keep multiple files for the same <deftype> separate.

When running under ISPF, the @ is replaced by a logical screen indicator (1, 2, ..9, A, B, ...). It is advisable to include a national character in this parameter, to avoid conflicts with predefined NEWLIST types.

DETAILHELPPANEL= *panel*
This indicates which help panel to use when there is no field level help panel available or requested and there is no DETAILHELPPANEL specified on the NEWLIST or OPTION statement, and HELP is pressed on the detail display of a DISPLAY or DSUMMARY. The panel name specified may contain "&CKREREL." to be replaced with 2 or 3 depending on the ISPF level (2 for VM), but not in the first position. If this parameter is omitted, C2R&CKREREL.NN#0 is used. The parameter must be specified before the field name, similar to the TYPE= specification.

HELPPANEL= *panel*
This indicates which help panel to use when there is no field level help panel available or requested and there is no help panel on the NEWLIST or OPTION statement appropriate for the current display level (HELPPANEL, or SUMHELPPANEL), and HELP is pressed on the summary or overview display of a DISPLAY or DSUMMARY. The panel name specified may contain "&CKREREL." to be replaced with 2 or 3 depending on the ISPF level (2 for VM), but not in the first position. If this parameter is omitted, C2R&CKREREL.NN@0 is used. The parameter must be specified before the field name, similar to the TYPE= specification.

NOWARN
This parameter can be used to turn off the check for national characters in the TYPE and ABBREV2 specifications. When this parameter is not specified, message CKR1308 is issued when no national character is used in either the TYPE or ABBREV2 specification. This message provides a warning about possible conflicts with predefined NEWLIST types that might occur.

TYPE= <*deftype*>
This sets the name of the DEFTYPE, to be used in the ALLOCATE/DEFINE and NEWLIST commands. It can be up to 24 characters long and can contain

characters, digits and the national characters. It is advisable to include a national character in this parameter, to avoid conflicts with predefined NEWLIST types.

DISPLAY

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•	•	•	•	•	•	•

You can use the DISPLAY command for showing the contents of arbitrary selected data interactively in an ISPF panel. When you create standard reports from the product menus, the DISPLAY command is automatically generated when needed. You only need to specify the command if you want to create customized ISPF panels. You can also specify the command using the abbreviation D. The command syntax is identical to the syntax for the LIST and SORTLIST commands, which is described in "LIST family of commands" on page 794. The sort order is the same order specified in the "SORTLIST" on page 918 command.

If the DISPLAYTOFILE format is specified, the DISPLAY command acts like a SORTLIST command if the PRINT or NEWLIST option is also set. This print specification turns an ISPF report into a batch report.

When a field in a DISPLAY statement is specified with the WORDWRAP or WRAP modifier, the field is shown in the Detail ISPF display panel but not in the Overview display panel.

DSUMMARY

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•	•	•	•	•	•	•

The DSUMMARY command is almost equal to the SUMMARY command, which is described in "SUMMARY" on page 918. The difference between the two is their behavior as influenced by the environment (ISPF or batch) and the combination with detailed information (when combined with DISPLAY or SORTLIST). The following table shows the difference in behavior.

	SORTLIST	DISPLAY	No detail
DSUMMARY	ISPF	ISPF	ISPF
SUMMARY	file	ISPF	file

The DSUMMARY command always generates an interactive ISPF summary, while the SUMMARY command only does so when combined with DISPLAY.

ENDBUNDLE

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

This command terminates a BUNDLE. The print options present before the BUNDLE command are restored.

ENDMERGE

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

This command terminates a MERGELIST. The options and scope determined by the last NEWLIST encountered (either in or before the MERGELIST) remain in effect. A subsequent NEWLIST is *not* merged.

This command is also used to end a MERGE command, see "MERGE" on page 836.

FILEOPTION

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

The `FILEOPTION` statement sets file options for the specified ddname. If you want to specify global file options, use the `OPTION` command. See "OPTION" on page 856.

The first `FILEOPTION` statement for a particular ddname also applies file options specified on previous `OPTION` statements insofar as these statements are not overridden by the FILEOPTION statement itself. Multiple FILEOPTION statements can be given for the same ddname, but they must precede the first NEWLIST that refers to that ddname. A NEWLIST can refer to a ddname explicitly by the DD= parameter, or implicitly by the DD= parameter of a previous OPTION command.

File options can also be specified on an individual NEWLIST. However, some file options must be the same for all NEWLISTs written to a particular ddname. You cannot override these options (FILEFORMAT=XMLand ENCODING=UTF-8 for example). Others can only be partially honored if they differ across newlists (e.g. NOPAGE and PAGELEN=nn influence whether a new data set gets allocated with RECFM=A or not).

Note that FILEOPTION can also be used for emailed newlists. If the emails are really emailed (not using option SMTPTOFILE) you should use DD=C2REMAIL on the FILEOPTION statement. If SMTPTOFILE is used, you should use DD=C2RSMTP.

As an example, the following commands write a "mount" report to DD MYREPOR1, which uses a page length of 64. The sensitivity report is written to the DD MYREPOR2 which uses a page length of 32.

```
fileoption dd=myrepor1 pagelength=64
fileoption dd=myrepor2 pagelength=32

option dd=myrepor1

newlist type=mount
 sortlist system mountpoint dsname volser

newlist type=sensitive dd=myrepor2
 sortlist auditpriority sensitivity dsname volser risk auditconcern
```

Note that for a MERGELIST the FILEOPTION parameters are taken from the first NEWLIST statement within the MERGELIST/ENDMERGE statement. The parameters from the other NEWLISTs are ignored.

The following parameters can be specified as FILEOPTION. The list describes what happens with NEWLISTs that *effectively* have this parameter (whether it is specified on a FILEOPTION command or directly on the NEWLIST).

CAPS
Output is only in uppercase.

Limitation: DBCS characters in the output for a `NEWLIST` statement are not affected by the `CAPS` option if the corresponding `NEWLIST` statement also has a DBCS option. In all other cases, including a listing of the input commands, DBCS characters are not preserved.

COMPRESS=[GZIP]
This parameter can be used to request that the output file is created in gzip format according to RFC 1952. This only works for UNIX files that have been allocated with an ALLOC command with a FILEDESC or PATH specification, see "ALLOCATE" on page 718. The default compression level of 6 is used. This parameter is invalid in combination with CMD, WTO, SNMP, and MAIL. It cannot be used with a DISPLAY command.

DD= *ddname*
ddname=*ddname*
FILE=*ddname* **F=***ddname*
This defines to which output file the FILEOPTION statement applies. This parameter is required.

ENCODING=EBCDIC
ENCODING=UTF-8
Output will be in the specified character encoding. By default the character encoding is EBCDIC. The advantage of UTF-8 output files is that values that are natively in Unicode format (e.g. Unicode DB2 fields) can in fact be processed preserving their value. The default, EBCDIC, means that any values in UTF-8 get converted to the best EBCDIC representation possible, exploiting substitute characters where no proper mapping exists.

Note that an UTF-8 file can be a Unix file or a data set. UTF-8 data sets cannot be processed well on the mainframe except to copy or FTP to another file format. Specifically, the ASA carriage control column in RECFM=VBA data sets will contain page or line feeds in UTF-8, and RECFM=VB files are not generated with a line feed per record at all.

The option ENCODING=UTF-8 is mutually exclusive with WTO, SNMP, and CMD.

If the proper `UNICODE` environment has not been set up, the `CKR0917` message is issued, and the run terminated. By suppressing this message, fallback to a simple low-128 ASCII translation scheme is possible, but this is not the best option for production purposes.

Example:

To sent out a UTF-8 encoded report in an email attachment, you can use the following CARLa.

```
fileoption dd=C2REMAIL encoding=UTF-8

newlist type=racf,
  mailto=rcpt@exampledomain.com,
```

```
 from=sender@exampledomain.com,
 outputformat=attach
select class=user segment=base special
sortlist key(8) pgmrname
```

FILEFORMAT=XML
FILEFORMAT=TEXT

This keyword can be used to specify the format of an output file. TEXT specifies that no special formatting will be done.

XML means that the output file should be in the form of an XML (Extended Markup Language) document. The specification of FILEFORMAT=XML is mutually exclusive with NEWLIST options WTO, CMD, SNMP, and PAGELENGTH, and with the DISPLAY command.

For any field written to be written to an FILEFORMAT=XML file, output modifiers TOPTITLE, TITLE, PAGE, PREFIX, and WRAP are forbidden. Literal strings currently have no meaning and are forbidden. However, a fixed literal content for an element can be created by a DEFINE element(HB ,"literal") TRUE.

The XML document generated will follow the general structure for XML: a header, a DTD (Document Type Definition) describing the document structure, and a single root element that contains the actual information output by LIST/SORTLIST/SUMMARY. The single root element is the ddname (filename) chosen. The root element has the `creation=` attribute for the creation time stamp in `xsd:dateTime` format. The structure of the rest of the document with the actual NEWLIST-specific output depends on whether there is a MERGELIST specification or not.

Without a MERGELIST, one data element per NEWLIST record will be written. The element name for a NEWLIST record is taken from the NEWLIST NAME= parameter. Hence this parameter is required with FILEFORMAT=XML. Within the NEWLIST record element, a sub-element will be present per non-empty field specified on the (SORT)LIST/SUMMARY statement. If the field is missing, then the sub-element will be omitted. When a field has multiple values, the sub-element will be repeated (unless the HORIZONTAL modifier is used). A field name can only occur once per NEWLIST. A field name cannot be the same as a NEWLIST name that is being output to the same XML document (output file).

Example:

```
fileoption dd=myxml fileformat=xml
n dd=myxml type=system name=SYS
 list system mvslvl
```

Creates XML document body:

```
<MYXML creation="2005-12-06T14:12:32.66+01:00">
<SYS>
<SYSTEM>DINO</SYSTEM>
<MVSLVL>SP7.0.4</MVSLVL>
</SYS>
</MYXML>
```

If there is a MERGELIST specification, the records within the mergelist are output as an element with a common name set to the MERGELIST NAME= parameter. The fields that are shared between all mergelist members are output as sub-elements of the NEWLIST type element. The non-shared fields are encapsulated in an element set to the member NEWLIST NAME= parameter (as for the non-MERGELIST, case but as a sub-element of the MERGELIST).

Example:

```
fileoption dd=myxml fileformat=xml
mergelist name=SOFTWARE dd=myxml
n type=system name=MVS
 list system mvslvl
n type=system name=ESM
 list system esmlvl
endmerge
```

Creates XML document body:

```
<MYXML creation="2005-12-07T15:23:04.78+01:00">
<SOFTWARE>
<SYSTEM>DINO</SYSTEM>
<MVS>
<MVSLVL>SP7.0.4</MVSLVL>
</MVS>
</SOFTWARE>
<SOFTWARE>
<SYSTEM>DINO</SYSTEM>
<ESM>
<ESMLVL>HRF7707 OA03853</ESMLVL>
</ESM>
</SOFTWARE>
</MYXML>
```

LINELEN= *value*
LINELENGTH=*value* **LL=***value*
This option can be used to set the length of lines that are output by Security zSecure. If Security zSecure controls the LRECL specification of the output DD (when calling from JCL with no LRECL= specification, or when dynamically allocating the data set), this parameter influences the LRECL of the resulting data set. Security zSecure uses the largest line length found for all NEWLISTs directed to a particular file. If Security zSecure writes to an existing data set, or LRECL= is specified for the file, the line length cannot become larger than this value.

To get the page number in the proper position for a narrow print, specify LL=79.

MAXP= *number*
MAXPAGE=*number*
PRTMAXP=*number*
This parameter can be used to limit the amount of output that is actually printed. All data is still read and formatted, but printing will stop the moment the specified number of pages has been reached.

NONULLS
This keyword can be specified to turn off the printing of hexadecimal nulls in the (sort)list report(s). They will be replaced with blanks. See also the NULLS keyword. Note that with XML output, trailing null characters are trimmed off; other null characters are replaced by · (a bullet character).

NOPAGE
This option suppresses all titles and headers which would normally be written above each page for sortlist output. If Security zSecure controls the RECFM specification of the output DD (when calling from JCL with no RECFM= specification, or when dynamically allocating the data set), and all NEWLISTs writing to this DD effectively have NOPAGE, then Security zSecure creates a RECFM=VB data set; otherwise a RECFM=VBA data set.

NOXML_DATADICT
This option turns off generating a data dictionary when XML output is requested (option FILEFORMAT=XML). See also option XML_DATADICT. By default the data dictionary is not generated.

NOXML_DTD
This option turns off generating a DTD (Document Type Definitions) when XML output is requested (option FILEFORMAT=XML). See also option XML_DTD. By default the DTD will be generated unless XML_STYLESHEET=IMBED has been specified.

NULLS
This keyword can be specified to turn on the printing of hexadecimal nulls in the (sort)list report(s). This is the default setting. See also the NONULLS keyword. Note that with XML output, trailing null characters are trimmed off; other null characters are replaced by · (a bullet character).

OVERPRINT= *number*
OVP=*number*
Number of overprints to get bold text on impact printers. Values must be in the range 0 to 9. Specifying 0 disables overprinting, and is the default. It is only used if the output file has RECFM=A and OPTCD=J is *not* included in the DCB parameters of the DD.

PAGELEN=number
PAGELENGTH=number PL=number
Number of lines on each page to be used for printing. The default is 0 for LIST commands in the domain of a NEWLIST, and 56 for SORTLIST commands, and for the files SYSPRINT and CKREPORT. The minimum is 6, the maximum is 32767.

PL=0 is equivalent to specifying NOPAGE, except that PL=0 prints page headers on the first page in the output file. You should use NOPAGE with (SORT)LIST to suppress page headers, e.g. for command generation.

If Security zSecure controls the RECFM specification of the output DD (when calling from JCL with no RECFM= specification, or when dynamically allocating the data set), and all NEWLISTs writing to this DD *effectively* have PL=0, then Security zSecure creates a RECFM=VB data set; otherwise a RECFM=VBA data set.

The PL= option is ignored with FILEFORMAT=XML; NOPAGE is implied instead.

SMTPCLASS= *sysoutclass*
Specifies the JES output class to be used for the SMTP output processing of emails. When no class is specified, email will be sent to the default class, B.

SMTPNJENODE= *nodename*
Specifies the JES destination to which emails will be routed for final processing. If the SMTP server is running on your local system, this keyword can be omitted.

SMTPWRITER= *name*
Specifies a name for use in SMTP selecting an email SYSOUT data set. The external writer name is equal to the SMTP address space name. When no writer is specified, email will be sent to the default writer, "SMTP".

TOPTITLE= *text*, **TT SUBTITLE=***text*, **ST TITLE=***text*, **T PAGETEXT=***text*
Titles to appear on subsequent output pages. TOPTITLE redefines the page header.

TOPTITLE is only used for LIST/SORTLIST/DISPLAY outside ISPF. TITLE redefines the title line printed below the top title line; SUBTITLE defines a line to be printed below the title line. TITLE and SUBTITLE are also used by DISPLAY commands inside ISPF and by REPORT and VERIFY output. The TOPTITLE parameter redefines the page header string only; the page indicator, page number and date are still printed. The PAGETEXT parameter can be used to redefine the page indicator, which is 'page' by default. The syntax requirements for the title are:

title='*string*'
title="*string*"
title=`*string* `
title=:*var*

The title string can be specified as a string enclosed in single, double or left quotation marks. The string can cross the line boundary, simply continue typing at the start of the next line. In the command listing, the string continuation is indicated by a + following the line number. Alternatively, an ISPF variable name can be passed prefixed by a colon. The content of the ISPF variable is used as the title. The implicit function pool, shared variable, and profile pool will be searched for the variable name.

See also “General output modifiers: Controlling field-related output” on page 798: title and toptitle.

XML_DATADICT
This option turns on generating a data dictionary when XML output is requested (option FILEFORMAT=XML). The data dictionary contains information about the characteristics of each generated report: the title, top title, and subtitle, and at the field level the field's format, its effective width, its alignment, its (prefix) header, and an indication whether it is a repeated field.

These formatting hints can be exploited by XSLT stylesheets so that many reports can be accommodated by a single stylesheet. Using a data dictionary is required when using the XSLT stylesheet supplied with IBM Security zSecure. See also option XML_STYLESHEET.

This option can be overridden with NOXML_DATADICT. By default the data dictionary is not generated.

XML_DTD
This option turns on generating a DTD (Document Type Definitions) specification when XML output is requested (option FILEFORMAT=XML). This specification can be used by XML processors to validate the document, and to get a better understanding of the structure of the XML document.

This option can be used to override an earlier NOXML_DTD. It cannot be specified when requesting an imbedded stylesheet using XML_STYLESHEET=IMBED. By default the DTD will be generated unless XML_STYLESHEET=IMBED has been specified. See also option NOXML_DTD.

XML_STYLESHEET=NO
XML_STYLESHEET=URI("*uri***")**
XML_STYLESHEET=IMBED(ddname=*ddname***,MEMBER=***member***)**
When `XML_STYLESHEET=URI("uri")` is specified, an `<?xml-stylesheet type="text/xsl" href="uri"?>` processing instruction is added to the prolog of the XML document. Make sure that the recipient of the report has access to the XSLT stylesheet identified by the URI specified in the processing instruction.
